

# CS2105

## An Awesome Introduction to Computer Networks

### Lecture 11: Network Security

Department of Computer Science  
School of Computing

# Lecture 11: Network Security

## *Chapter goals:*

- understand principles of network security:
  - cryptography and its *many* uses beyond “confidentiality”
  - authentication
  - message integrity
- security in practice:
  - firewalls and intrusion detection systems
  - security in application, transport, network, link layers

# Chapter 8 roadmap

*8.1 What is network security?*

8.2 Principles of cryptography

8.3 Message integrity and digital signatures

8.7 Network layer security: VPNs

8.9 Operational security: firewalls

# What is network security?

***confidentiality:*** only sender, intended receiver should “understand” message contents

- sender encrypts message
- receiver decrypts message

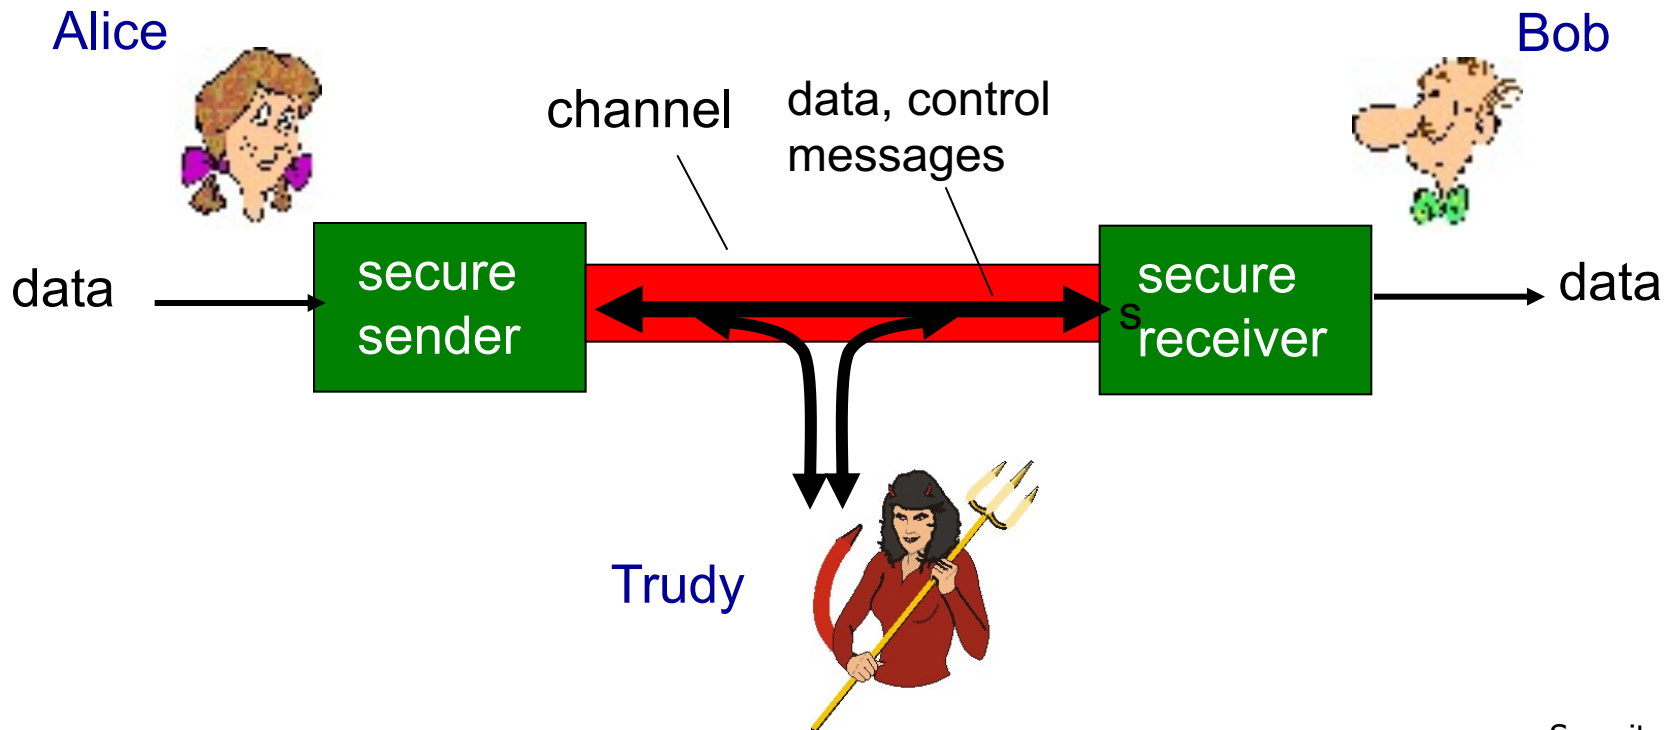

***authentication:*** sender, receiver want to confirm identity of each other

***message integrity:*** sender, receiver want to ensure message not altered (in transit, or afterwards) without detection

***access and availability:*** services must be accessible and available to users

# Friends and enemies: Alice, Bob, Trudy

- well-known in network security world
- Bob, Alice (lovers!) want to communicate “securely”
- Trudy (intruder) may intercept, delete, add messages

# Who might Bob, Alice be?

- ... well, *real-life* Bobs and Alices!
- Web browser/server for electronic transactions (e.g., on-line purchases)
- on-line banking client/server
- DNS servers
- routers exchanging routing table updates
- other examples?

# There are bad guys (and girls) out there!

Q: What can a “bad guy” do?

A: A lot!

- *eavesdrop*: intercept messages
- actively *insert* messages into connection
- *impersonation*: can fake (spoof) source address in packet (or any field in packet)
- *hijacking*: “take over” ongoing connection by removing sender or receiver, inserting himself in place
- *denial of service*: prevent service from being used by others (e.g., by overloading resources)

# Chapter 8 roadmap

8.1 What is network security?

8.2 *Principles of cryptography*

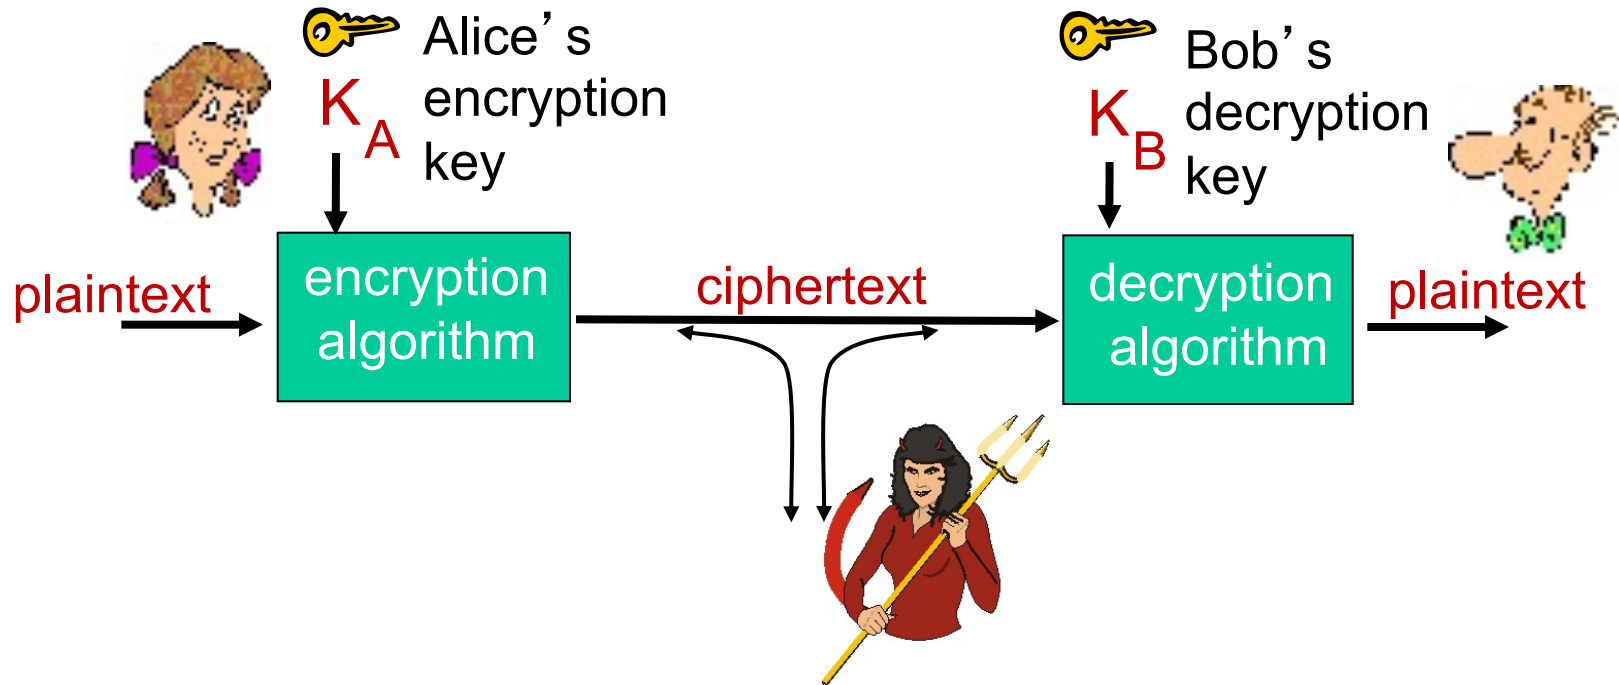

8.3 Message integrity and digital signatures

8.7 Network layer security: VPNs

8.9 Operational security: firewalls

# The language of cryptography

$m$  plaintext message

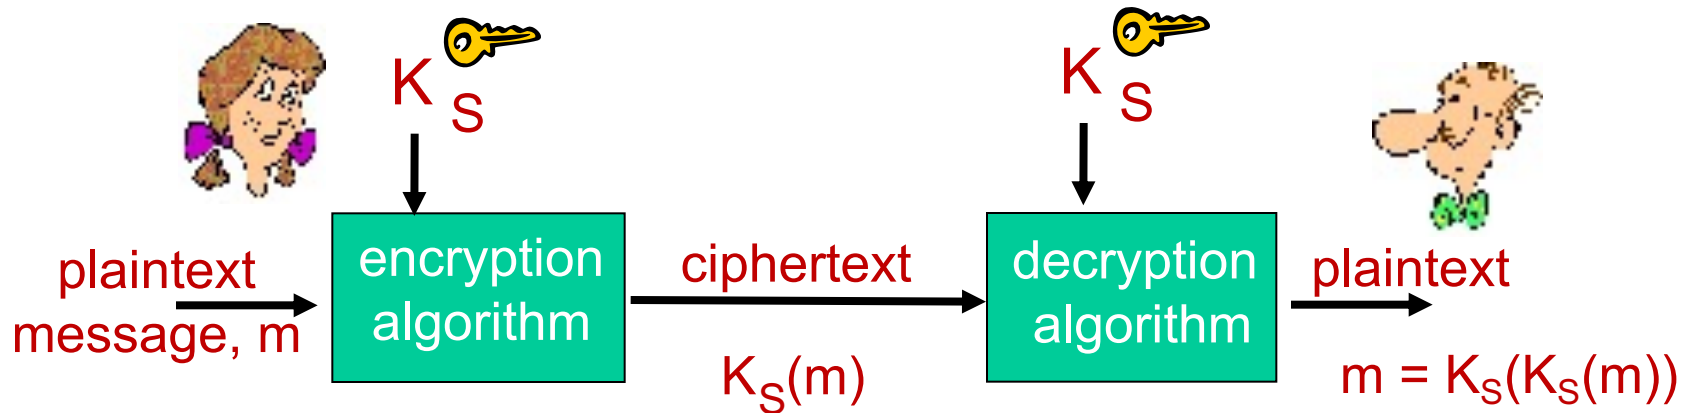

$K_A(m)$  ciphertext, encrypted with key  $K_A$

$m = K_B(K_A(m))$

# Breaking an encryption scheme

- **cipher-text only attack:**  
Trudy has ciphertext she can analyze
- **two approaches:**
  - brute force: search through all keys
  - statistical analysis
- **known-plaintext attack:**  
Trudy has plaintext corresponding to ciphertext
  - e.g., in monoalphabetic cipher, Trudy determines pairings for a,l,i,c,e,b,o,
- **chosen-plaintext attack:**  
Trudy can get ciphertext for chosen plaintext

# Symmetric key cryptography

**symmetric key crypto:** Bob and Alice share same (symmetric) key:  $K_S$

- e.g., key is knowing substitution pattern in mono alphabetic substitution cipher

**Q:** how do Bob and Alice agree on key value?

# Simple encryption scheme

*substitution cipher*: substituting one thing for another

- monoalphabetic cipher: substitute one letter for another

plaintext:	a	b	c	d	e	f	g	h	i	j	k	l	m	n	o	p	q	r	s	t	u	v	w	x	y	z
		↓																								↓
ciphertext:	m	n	b	v	c	x	z	a	s	d	f	g	h	j	k	l	p	o	i	u	y	t	r	e	w	q

e.g.: Plaintext: bob. i love you. alice  
ciphertext: nkn. s gktc wky. mgsbc

🔑 *Encryption key*: mapping from set of 26 letters  
to set of 26 letters

# Side-note: Caesar's cipher

- This method is named after Julius Caesar, who used it in his private correspondence
- Fixed shift of alphabet, e.g., left rotation by 3 (or right by 23):

plaintext:   abcdefghijklmnopqrstuvwxyz  
                  ↓                  ↘                  ↓  
ciphertext:   xyzabcdefghijklmnopqrstuvw

e.g.:       plaintext: the quick brown fox  
              ciphertext: qeb nrfzh yoltk clu

🔑 *Encryption key:* only need shift number

# A more sophisticated encryption approach

- n substitution ciphers,  $M_1, M_2, \dots, M_n$
- cycling pattern:
  - e.g.,  $n=4$ :  $M_1, M_3, M_4, M_3, M_2$ ;  $M_1, M_3, M_4, M_3, M_2$ ; ..
- for each new plaintext symbol, use subsequent substitution pattern in cyclic pattern
  - dog: d from  $M_1$ , o from  $M_3$ , g from  $M_4$

*Encryption key:* n substitution ciphers, and cyclic pattern

- key need not be just n-bit pattern

# Symmetric key crypto: DES

## DES: Data Encryption Standard

- US encryption standard [NIST 1993]
- 56-bit symmetric key, 64-bit plaintext input
- block cipher with cipher block chaining
- how secure is DES?
  - DES Challenge: 56-bit-key-encrypted phrase decrypted (brute force) in less than a day
  - no known good analytic attack
- making DES more secure:
  - 3DES: encrypt 3 times with 3 different keys

# AES: Advanced Encryption Standard

- symmetric-key NIST standard, replaced DES (Nov 2001)
- processes data in 128 bit blocks
- 128, 192, or 256 bit keys
- brute force decryption (try each key) taking 1 sec on DES, takes 149 trillion years for AES

 adding 1 bit will double the amount of time to brute force

# Public Key Cryptography

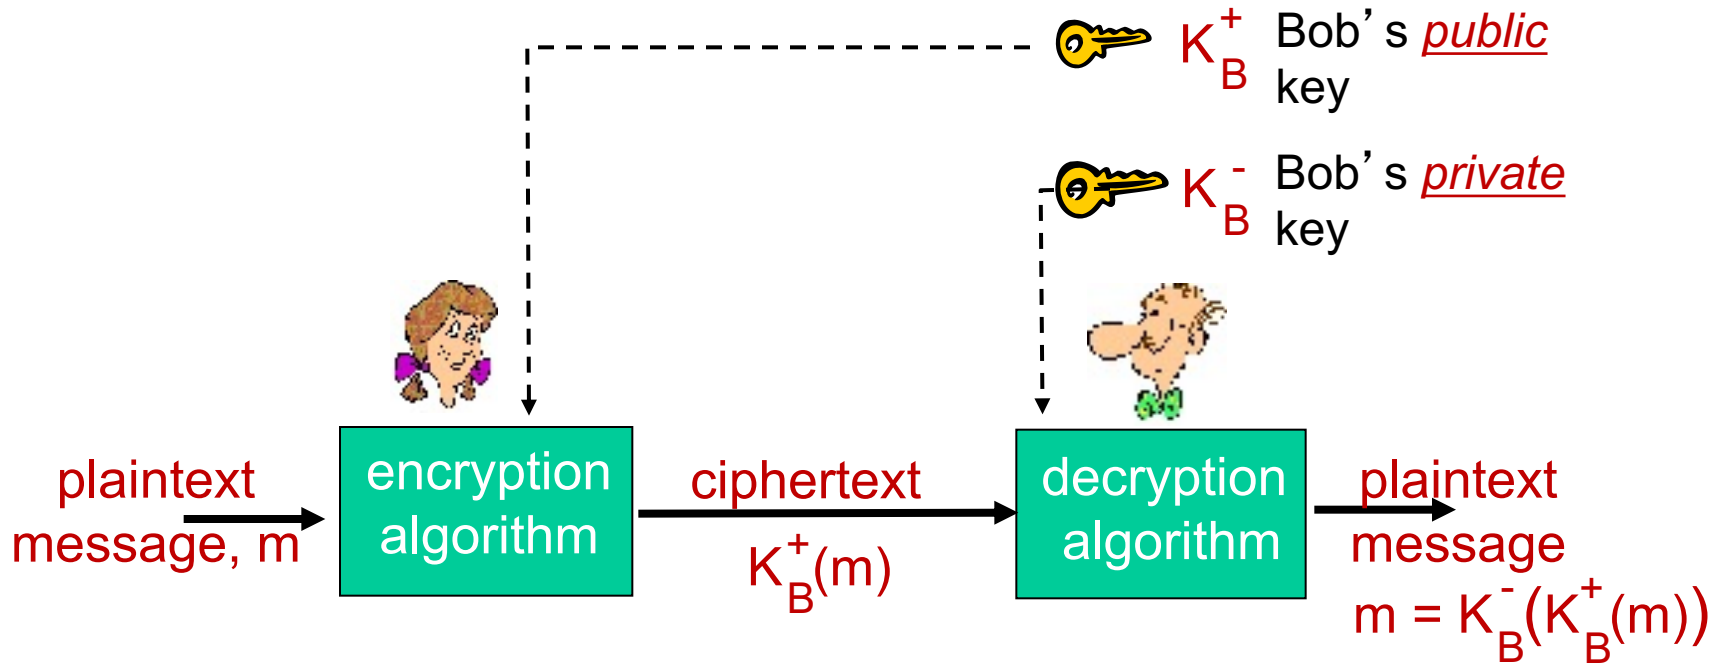

## *symmetric key crypto*

- requires sender, receiver know shared secret key
- Q: how to agree on key in first place (particularly if never “met”)?

## *public key crypto*

- radically different approach [Diffie-Hellman’76, RSA’78]
- sender, receiver do *not* share secret key
- *public* encryption key known to *all*
- *private* decryption key known only to receiver

# Public key cryptography

# Public key encryption algorithms

requirements:

- ① need  $K_B^+(\cdot)$  and  $K_B^-(\cdot)$  such that

$$K_B^-(K_B^+(m)) = m$$

- ② given public key  $K_B^+$ , it should be impossible to compute private key  $K_B^-$

**RSA:** Rivest, Shamir, Adleman algorithm

# Prerequisite: modular arithmetic

- $x \bmod n$  = remainder of  $x$  when divide by  $n$

- facts:

$$[(a \bmod n) + (b \bmod n)] \bmod n = (a+b) \bmod n$$

$$[(a \bmod n) - (b \bmod n)] \bmod n = (a-b) \bmod n$$

$$[(a \bmod n) * (b \bmod n)] \bmod n = (a*b) \bmod n$$

- thus

$$(a \bmod n)^d \bmod n = a^d \bmod n$$

- example:  $x=14$ ,  $n=10$ ,  $d=2$ :

$$(x \bmod n)^d \bmod n = 4^2 \bmod 10 = 6$$

$$x^d = 14^2 = 196 \quad x^d \bmod 10 = 6$$

# RSA: getting ready

- message: just a bit pattern
- bit pattern can be uniquely represented by an integer number
- thus, encrypting a message is equivalent to encrypting a number

## *example:*

- $m = 10010001$ . This message is uniquely represented by the decimal number 145.
- to encrypt  $m$ , we encrypt the corresponding number, which gives a new number (the ciphertext).

# RSA: Creating public/private key pair

1. choose two large prime numbers  $p, q$ .  
(e.g., 1024 bits each)
2. compute  $n = pq$ ,  $z = (p-1)(q-1)$
3. choose  $e$  (with  $e < n$ ) that has no common factors with  $z$  ( $e, z$  are “relatively prime”).
4. choose  $d$  such that  $ed-1$  is exactly divisible by  $z$ .  
(in other words:  $ed \bmod z = 1$  ).
5. public key is  $\underbrace{(n, e)}_{K_B^+}$ . private key is  $\underbrace{(n, d)}_{K_B^-}$ .

# RSA: encryption, decryption

0. given  $(n,e)$  and  $(n,d)$  as computed above

1. to encrypt message  $m$  ( $<n$ ), compute

$$c = m^e \bmod n$$

2. to decrypt received bit pattern,  $c$ , compute

$$m = c^d \bmod n$$

*magic happens!*

$$m = \underbrace{(m^e \bmod n)}_c^d \bmod n$$

# RSA example:

Bob chooses  $p=5$ ,  $q=7$ . Then  $n=35$ ,  $z=24$ .

$e=5$  (so  $e$ ,  $z$  relatively prime).

$d=29$  (so  $ed-1$  exactly divisible by  $z$ ).

encrypting 8-bit messages.

# Why does RSA work?

- must show that  $c^d \bmod n = m$   
where  $c = m^e \bmod n$
- fact: for any  $x$  and  $y$ :  $x^y \bmod n = x^{(y \bmod z)} \bmod n$ 
  - where  $n = pq$  and  $z = (p-1)(q-1)$
- thus,  
$$\begin{aligned} c^d \bmod n &= (m^e \bmod n)^d \bmod n \\ &= m^{ed} \bmod n \\ &= m^{(ed \bmod z)} \bmod n \\ &= m^1 \bmod n \\ &= m \end{aligned}$$

# RSA: another important property

The following property will be *very* useful later:

$$\underbrace{K_B^-(K_B^+(m))}_{\text{use public key first, followed by private key}} = m = \underbrace{K_B^+(K_B^-(m))}_{\text{use private key first, followed by public key}}$$

use public key first,  
followed by  
private key

use private key  
first, followed by  
public key

*result is the same!*

**Why**  $K_B^-(K_B^+(m)) = m = K_B^+(K_B^-(m))$  ?

---

follows directly from modular arithmetic:

$$\begin{aligned}(m^e \bmod n)^d \bmod n &= m^{ed} \bmod n \\ &= m^{de} \bmod n \\ &= (m^d \bmod n)^e \bmod n\end{aligned}$$

# Why is RSA secure?

- suppose you know Bob's public key  $(n,e)$ . How hard is it to determine  $d$ ?
- essentially need to find factors of  $n$  without knowing the two factors  $p$  and  $q$ 
  - fact: factoring a big number is hard

# RSA in practice: session keys

- exponentiation in RSA is computationally intensive
- DES is at least 100 times faster than RSA
- use public key crypto to establish secure connection, then establish second key – **symmetric session key** – for encrypting data

## *session key, $K_S$*

- Bob and Alice use RSA to exchange a symmetric key  $K_S$
- once both have  $K_S$ , they use symmetric key cryptography

# Recommended key lengths

## ■ Recommendations [Lenstra and Verheul]

	1982	1995	2002	2010	2020	2030	2040
Sym	56	66	72	78	86	93	101
RSA	417	777	1028	1369	1881	2493	3214

## ■ Bruce Schneier's Applied Cryptography, p.18

- Probability to get hit by lightning per day ( $10^{-10}$ ,  $2^{-33}$ )
- Number of atoms on earth ( $10^{51}$ ,  $2^{170}$ )
- Number of atoms in the universe ( $10^{77}$ ,  $2^{265}$ )
- Time until next ice age (14,000,  $2^{14}$  years)
- Duration until sun goes nova ( $10^9$ ,  $2^{30}$  years)
- Age of the Universe ( $10^{10}$ ,  $2^{33}$  years)

# Chapter 8 roadmap

8.1 What is network security?

8.2 Principles of cryptography

8.3 *Message integrity and digital signatures*

8.7 Network layer security: VPNs

8.9 Operational security: firewalls

# Digital signatures

cryptographic technique analogous to hand-written signatures:

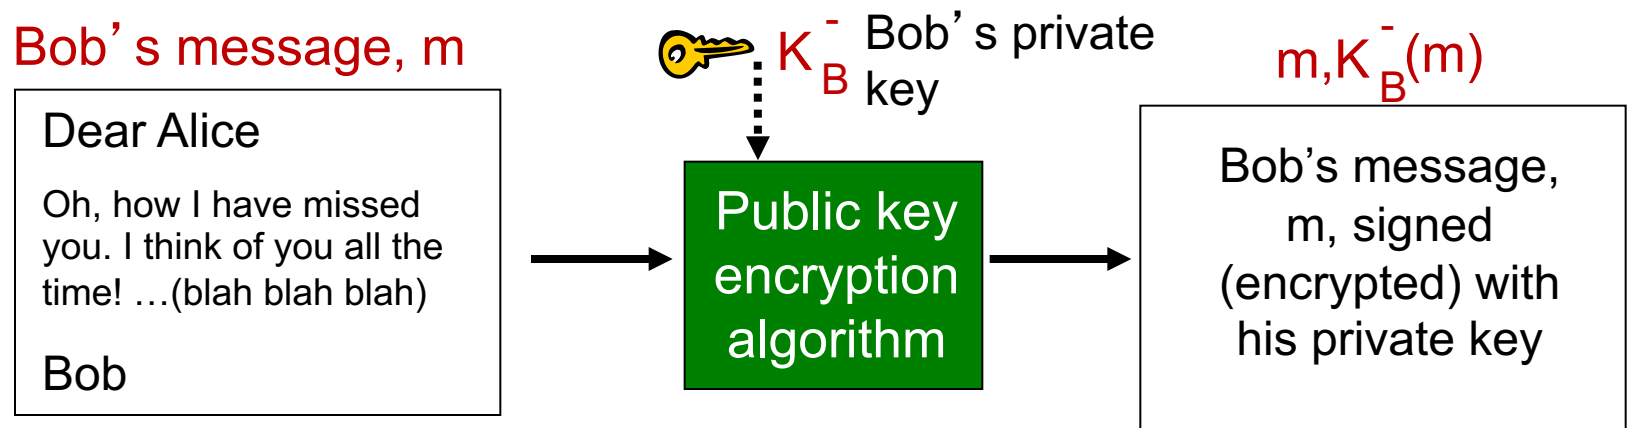

- sender (Bob) digitally signs document, establishing he is document owner/creator.
- *verifiable, nonforgeable*: recipient (Alice) can prove to someone that Bob, and no one else (including Alice), must have signed document

# Digital signatures

## simple digital signature for message $m$ :

- Bob signs  $m$  by encrypting with his private key  $K_B^-$ , creating “signed” message,  $K_B^-(m)$

Embedding the plaintext here is just as a concept - since usually signing a document will still allow the document to be read normally

# Digital signatures

- Suppose Alice receives msg  $m$ , with signature:  $m, K_B^-(m)$ .
- Alice verifies  $m$  signed by Bob by applying Bob's public key  $K_B^+$  to  $K_B^-(m)$  then checks  $K_B^+(K_B^-(m)) = m$ .
- If  $K_B^+(K_B^-(m)) = m$ , whoever signed  $m$  must have used Bob's private key.

Alice thus verifies that:

- Bob signed  $m$
- no one else signed  $m$
- Bob signed  $m$  and not  $m'$

non-repudiation:

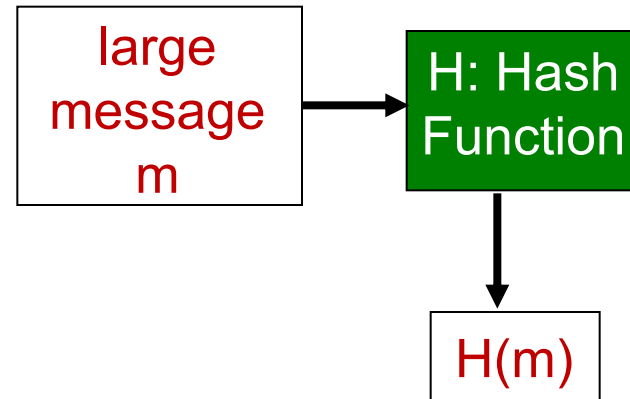

- ✓ Alice can take  $m$ , and signature  $K_B^-(m)$  to court and prove that Bob signed  $m$

# Message digests

computationally expensive to public-key-encrypt long messages

**goal:** fixed-length, easy-to-compute digital “fingerprint”

- apply hash function  $H$  to  $m$ , get fixed size message digest,  $H(m)$ .

Hash function properties:

- many-to-1
- produces fixed-size msg digest (fingerprint)
- given message digest  $x$ , computationally infeasible to find  $m$  such that  $x = H(m)$

# Internet checksum: poor crypto hash function

Internet checksum has some properties of hash function:

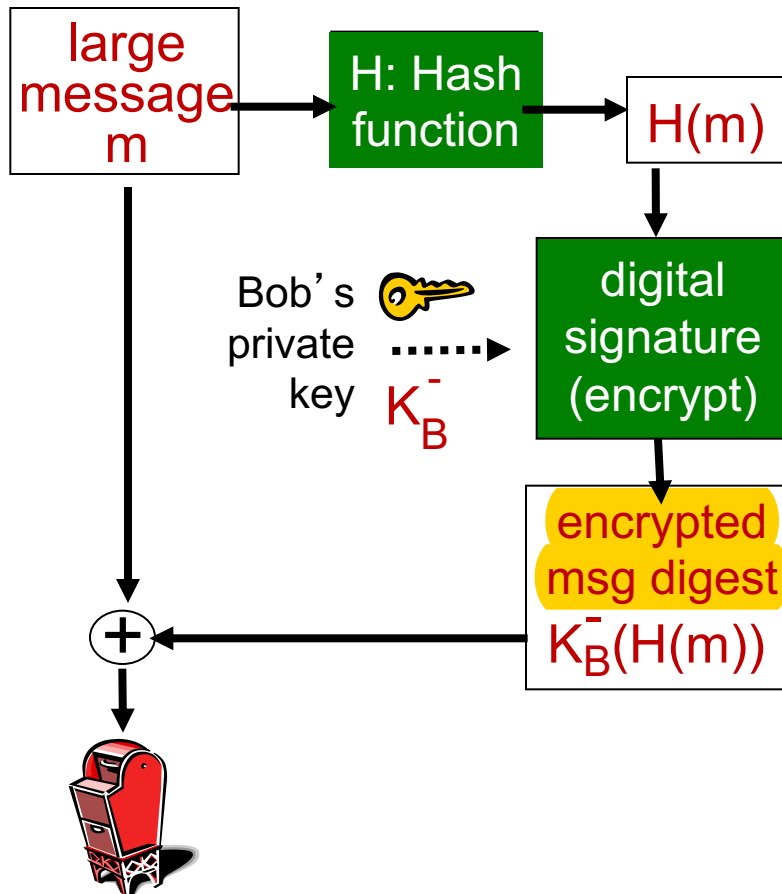

- produces fixed length digest (16-bit sum) of message
- is many-to-one

But given message with given hash value, it is easy to find another message with same hash value:

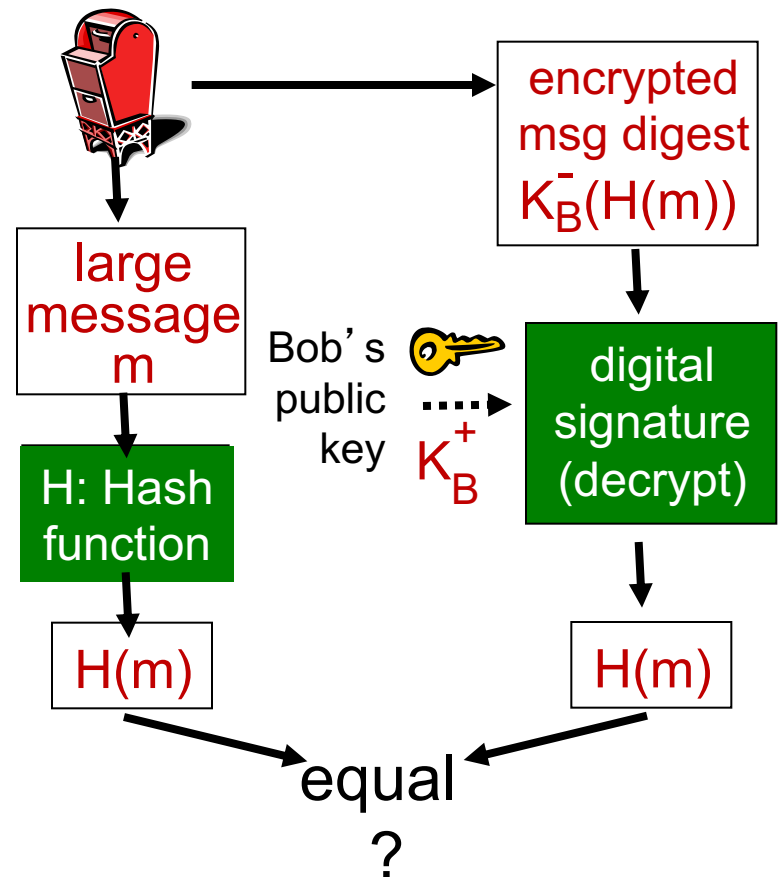

<u>message</u>	<u>ASCII format</u>		<u>message</u>	<u>ASCII format</u>
I O U 1	49 4F 55 31		I O U <u>9</u>	49 4F 55 <u>39</u>
0 0 . 9	30 30 2E 39		0 0 . <u>1</u>	30 30 2E <u>31</u>
9 B O B	39 42 D2 42		9 B O B	39 42 D2 42
<hr/>			<hr/>	
	B2 C1 D2 AC	different messages but identical checksums!		B2 C1 D2 AC

# Digital signature = signed message digest

Bob sends digitally signed message:

Alice verifies signature, integrity of digitally signed message:

# Hash function algorithms

- **MD5 hash function widely used (RFC 1321)**
  - computes 128-bit message digest in 4-step process.
  - arbitrary 128-bit string  $x$ , appears difficult to construct msg  $m$  whose MD5 hash is equal to  $x$
- **SHA-1 is also used**
  - US standard [NIST, FIPS PUB 180-1]
  - 160-bit message digest

# Hash function, e.g., md5sum (I)

- Generate short, fixed-length outputs (or digests); 128 bits
  - especially useful for longer inputs; “fingerprint”

```
$ cat smallfile
This is a very small file with a few characters

$ cat bigfile
This is a larger file that contains more characters.
This demonstrates that no matter how big the input
stream is, the generated hash is the same size (but
of course, not the same value). If two files have
a different hash, they surely contain different data.

$ ls -l empty-file smallfile bigfile linux-kernel
-rw-rw-r-- 1 steve steve 0 2004-08-20 08:58 empty-file
-rw-rw-r-- 1 steve steve 48 2004-08-20 08:48 smallfile
-rw-rw-r-- 1 steve steve 260 2004-08-20 08:48 bigfile
-rw-r--r-- 1 root root 1122363 2003-02-27 07:12 linux-kernel

$ md5sum empty-file smallfile bigfile linux-kernel
d41d8cd98f00b204e9800998ecf8427e empty-file
75cdbfeb70a06d42210938da88c42991 smallfile

```

# Hash function, e.g., md5sum (2)

- A small change in the input should result in a large change in the hash output

```
$ cat file1
This is a very small file with a few characters

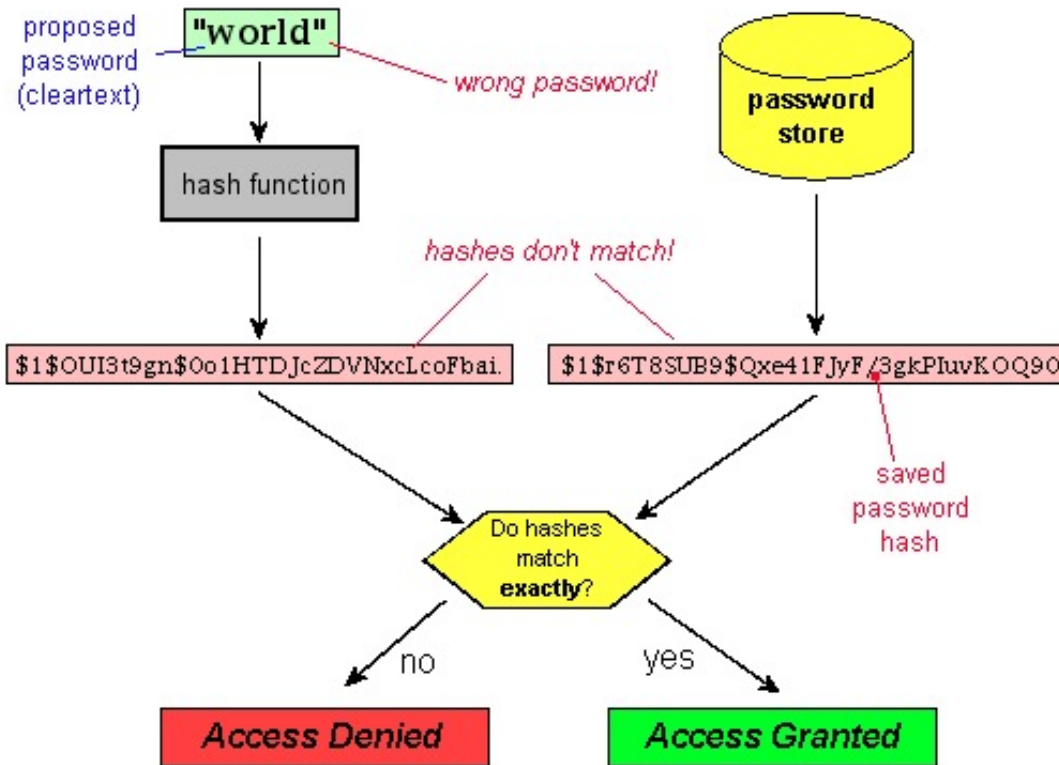

$ cat file2
this is a very small file with a few characters

$ md5sum file?
75cdbfeb70a06d42210938da88c42991  file1
6fbe37f1eea0f802bd792ea885cd03e2  file2
```

# Password hashing

- Passwords are not stored in plaintext but hashed and stored

**Fig. 5: Testing a proposed password against the stored hash**

# Public-key certification

- motivation: Trudy plays pizza prank on Bob
  - Trudy creates e-mail order:  
*Dear Pizza Store, Please deliver to me four pepperoni pizzas. Thank you, Bob*
  - Trudy signs order with her private key
  - Trudy sends order to Pizza Store
  - Trudy sends to Pizza Store her public key, but says it's Bob's public key
  - Pizza Store verifies signature; then delivers four pepperoni pizzas to Bob
  - Bob doesn't even like pepperoni

# Certification authorities

- **certification authority (CA):** binds public key to particular entity, E.
- E (person, router) registers its public key with CA.
  - E provides “proof of identity” to CA.
  - CA creates certificate binding E to its public key.
  - certificate containing E’s public key digitally signed by CA – CA says “this is E’s public key”

# Certification authorities

- when Alice wants Bob's public key:
  - gets Bob's certificate (Bob or elsewhere).
  - apply CA's public key to Bob's certificate, get Bob's public key

# Chapter 8 roadmap

8.1 What is network security?

8.2 Principles of cryptography

8.3 Message integrity and digital signatures

*8.7 Network layer security: VPNs*

8.9 Operational security: firewalls

# Virtual Private Networks (VPNs)

## *motivation:*

- institutions often want private networks for security.
  - costly: separate routers, links, DNS infrastructure.
- VPN: institution's inter-office traffic is sent over public Internet instead
  - encrypted before entering public Internet
  - logically separate from other traffic

# Virtual Private Networks (VPNs)

# Chapter 8 roadmap

8.1 What is network security?

8.2 Principles of cryptography

8.3 Message integrity and digital signatures

8.7 Network layer security: VPNs

*8.9 Operational security: firewalls*

# Firewalls

## *firewall*

isolates organization's internal net from larger Internet, allowing some packets to pass, blocking others

# Firewalls: why

prevent denial of service attacks:

- SYN flooding: attacker establishes many bogus TCP connections, no resources left for “real” connections

prevent illegal modification/access of internal data

- e.g., attacker replaces CIA’s homepage with something else

allow only authorized access to inside network

- set of authenticated users/hosts

three types of firewalls:

- stateless packet filters
- stateful packet filters
- application gateways

# Stateless packet filtering

- internal network connected to Internet via *router firewall*
- router *filters packet-by-packet*, decision to forward/drop packet based on:
  - source IP address, destination IP address
  - TCP/UDP source and destination port numbers
  - ICMP message type
  - TCP SYN and ACK bits

# Stateless packet filtering: example

- *example 1*: block incoming and outgoing datagrams with IP protocol field = 17 and with either source or dest port = 23
  - *result*: all incoming, outgoing UDP flows and telnet connections are blocked
- *example 2*: block inbound TCP segments with ACK=0.
  - *result*: prevents external clients from making TCP connections with internal clients, but allows internal clients to connect to outside.

# Stateless packet filtering: more examples

<i>Policy</i>	<i>Firewall Setting</i>
No outside Web access.	Drop all outgoing packets to any IP address, port 80
No incoming TCP connections, except those for institution's public Web server only.	Drop all incoming TCP SYN packets to any IP except 130.207.244.203, port 80
Prevent Web-radios from eating up the available bandwidth.	Drop all incoming UDP packets - except DNS and router broadcasts.
Prevent your network from being used for a smurf DoS attack.	Drop all ICMP packets going to a "broadcast" address (e.g. 130.207.255.255).
Prevent your network from being tracerouted	Drop all outgoing ICMP TTL expired traffic

# Stateful packet filtering

- *stateless packet filter*: heavy handed tool
  - admits packets that “make no sense,” e.g., dest port = 80, ACK bit set, even though no TCP connection established:

action	source address	dest address	protocol	source port	dest port	flag bit
allow	outside of 222.22/16	222.22/16	TCP	80	> 1023	ACK

- *stateful packet filter*: track status of every TCP connection
  - track connection setup (SYN), teardown (FIN): determine whether incoming, outgoing packets “makes sense”
  - timeout inactive connections at firewall: no longer admit packets

# Stateful packet filtering

ACL augmented to indicate need to check connection state table before admitting packet

action	source address	dest address	proto	source port	dest port	flag bit	check conxion
allow	222.22/16	outside of 222.22/16	TCP	> 1023	80	any	
allow	outside of 222.22/16	222.22/16	TCP	80	> 1023	ACK	X
allow	222.22/16	outside of 222.22/16	UDP	> 1023	53	---	
allow	outside of 222.22/16	222.22/16	UDP	53	> 1023	----	X
deny	all	all	all	all	all	all	

# Application gateways

- filter packets on application data as well as on IP/TCP/UDP fields.
- *example:* allow select internal users to telnet outside

1. require all telnet users to telnet through gateway.
2. for authorized users, gateway sets up telnet connection to dest host. Gateway relays data between 2 connections
3. router filter blocks all telnet connections not originating from gateway.

# Limitations of firewalls, gateways

- *IP spoofing*: router can't know if data “really” comes from claimed source
- if multiple app's. need special treatment, each has own app. gateway
- client software must know how to contact gateway.
  - e.g., must set IP address of proxy in Web browser
- filters often use all or nothing policy for UDP
- *tradeoff*: degree of communication with outside world, level of security
- many highly protected sites still suffer from attacks

# Network Security (summary)

## basic techniques.....

- cryptography (symmetric and public)
- message integrity, digital signatures
- end-point authentication

## .... used in many different security scenarios (not covered in lecture)

- secure email
- secure transport (SSL)
- IP sec
- 802.11

## operational security: firewalls and VPNs
