# Lecture 5: Network Security

5.1 Background

5.2 Attack on Naming

5.3 Denial of Service attack

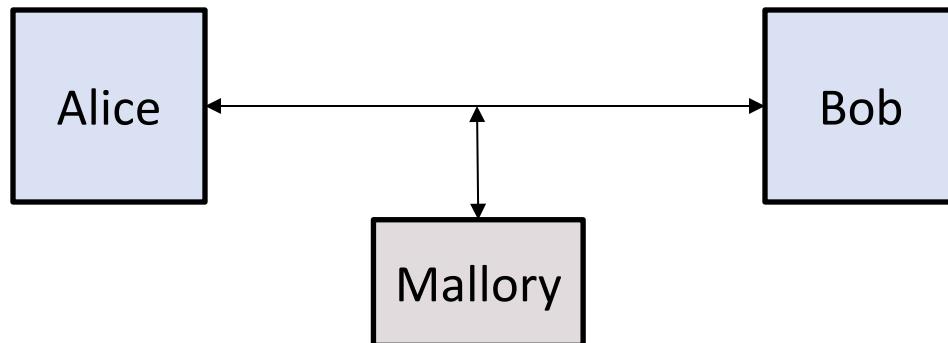

5.4 Useful tools

5.5 Protection: Securing the Channel using Cryptography

5.6 Protection: Firewall, Intrusion Detection System

5.7 Protection: Management

- Previous lectures illustrate that, using cryptographic techniques + PKI, we can secure the public communication channel between Alice and Bob, so as to achieve ***authenticity & confidentiality***.

- Mission accomplished? There are many other issues:
  1. Other security requirements (e.g. availability, anonymity, access control);
  2. Other information, in particular networking information, to be protected (e.g. DNS, routing information);
  3. Access control, monitoring and other management issue (e.g. firewall) ;
  4. etc

# 5.1 Background on Networking

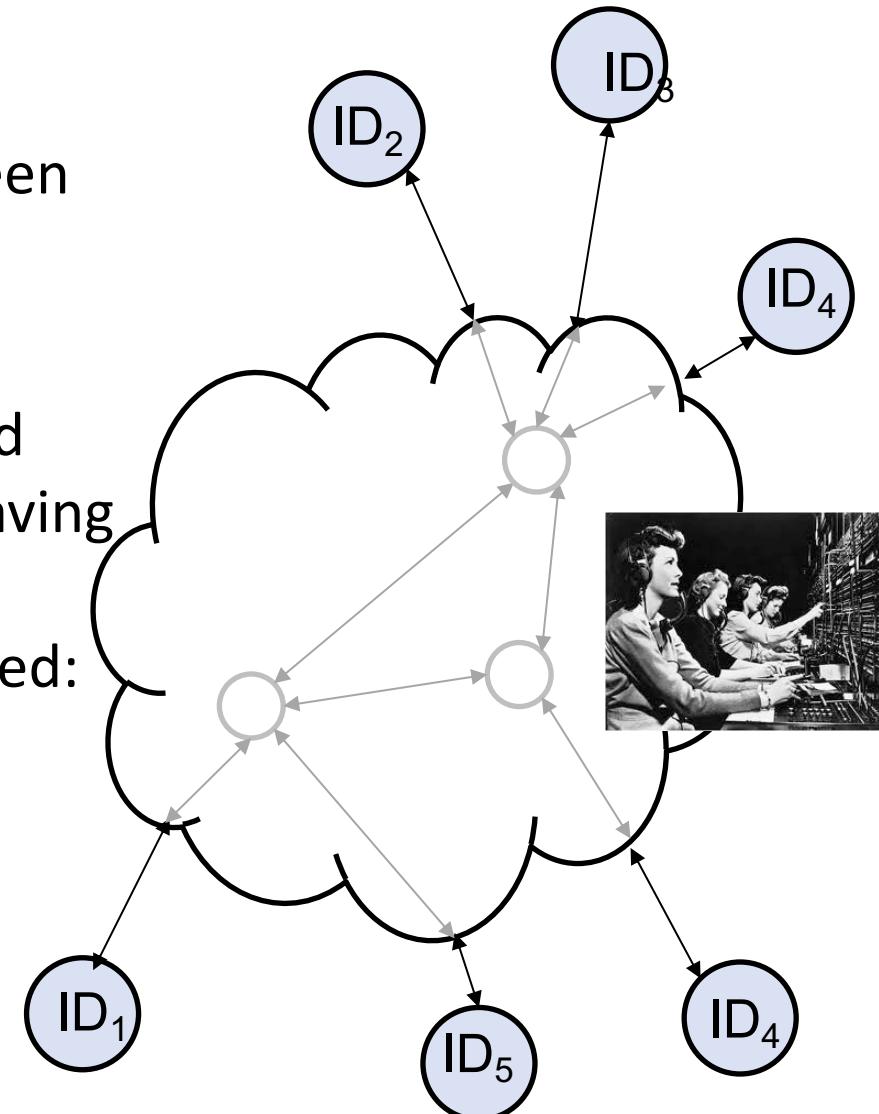

Important notions for this module:

- Layers
- Naming
- Ports

# Computer Network

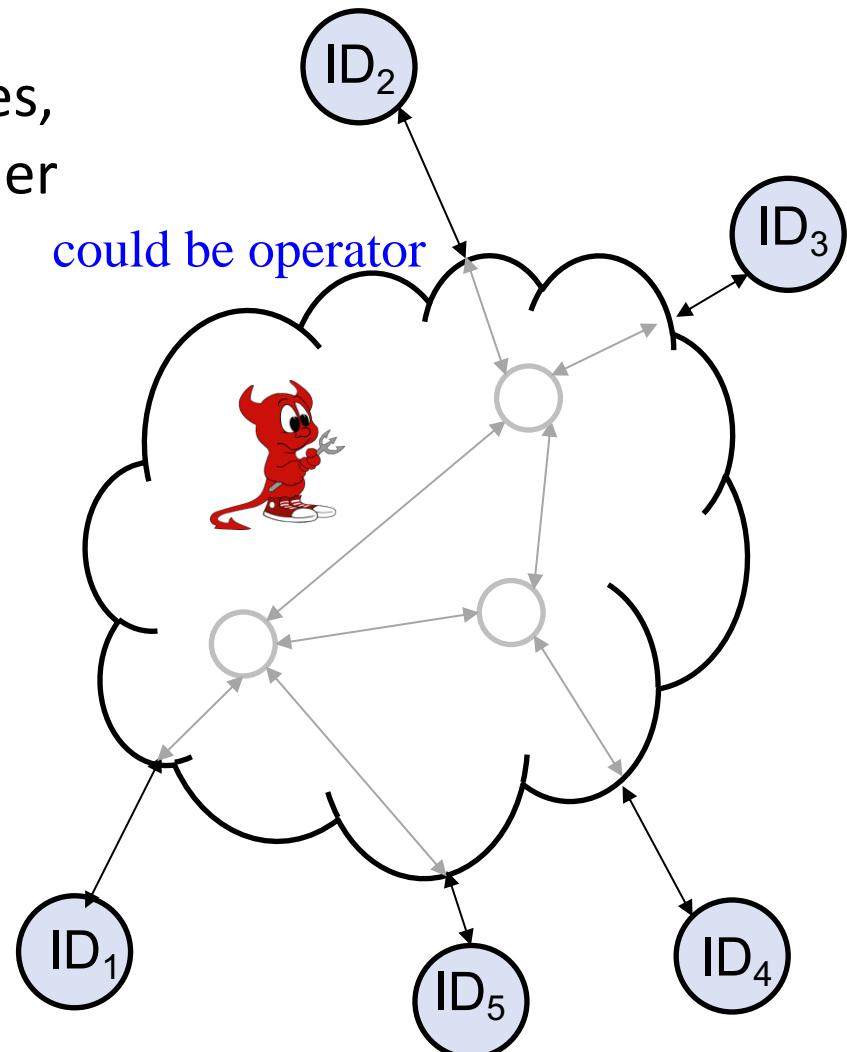

laying 1 line for every pair is not feasible,  
since need  $n^2$

- Computer Network establishes communicating connection between entities.
- To share networking resources and enhance robustness, instead of having dedicated line between any two nodes, **packet switching** is deployed:
  1. Messages route via multiple switches and routers.
  2. Messages are broken into “packets/frames”.

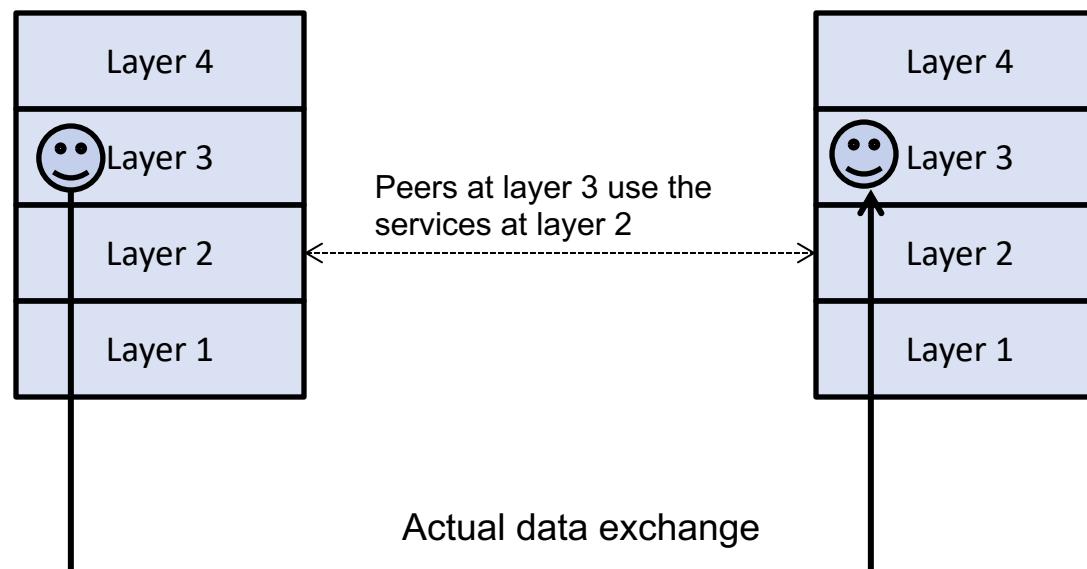

# Network Security

- While networking technologies focus on how to deliver messages, network security focus on another aspect. Under the presences of attackers:
  - Preserving confidentiality and authenticity of the messages and various entities;
  - Maintaining availability of the network;
  - Controlling and monitoring the traffic flow.

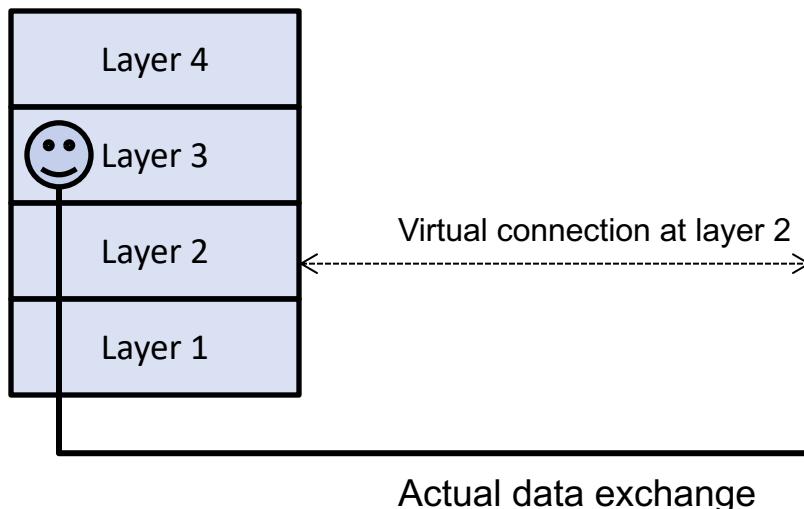

# Network layers

- Network protocols are abstracted as layers.
- Conceptually, layer (N-1) provides services for entities in layer N. The *peer entities* in the N layer communicate by executing protocols provided by layer (N-1).

# Network layers

- In other words, the layer N services/protocols are built on top of services provided by layer (N-1). We can view the services at (N-1) as a virtual connection.
- In turn, the layer N can provide services for (N+1).
- The actual data sent by layer N are often divided into smaller units, and each unit is called a PDU (protocol data unit).

A hypothetical example:

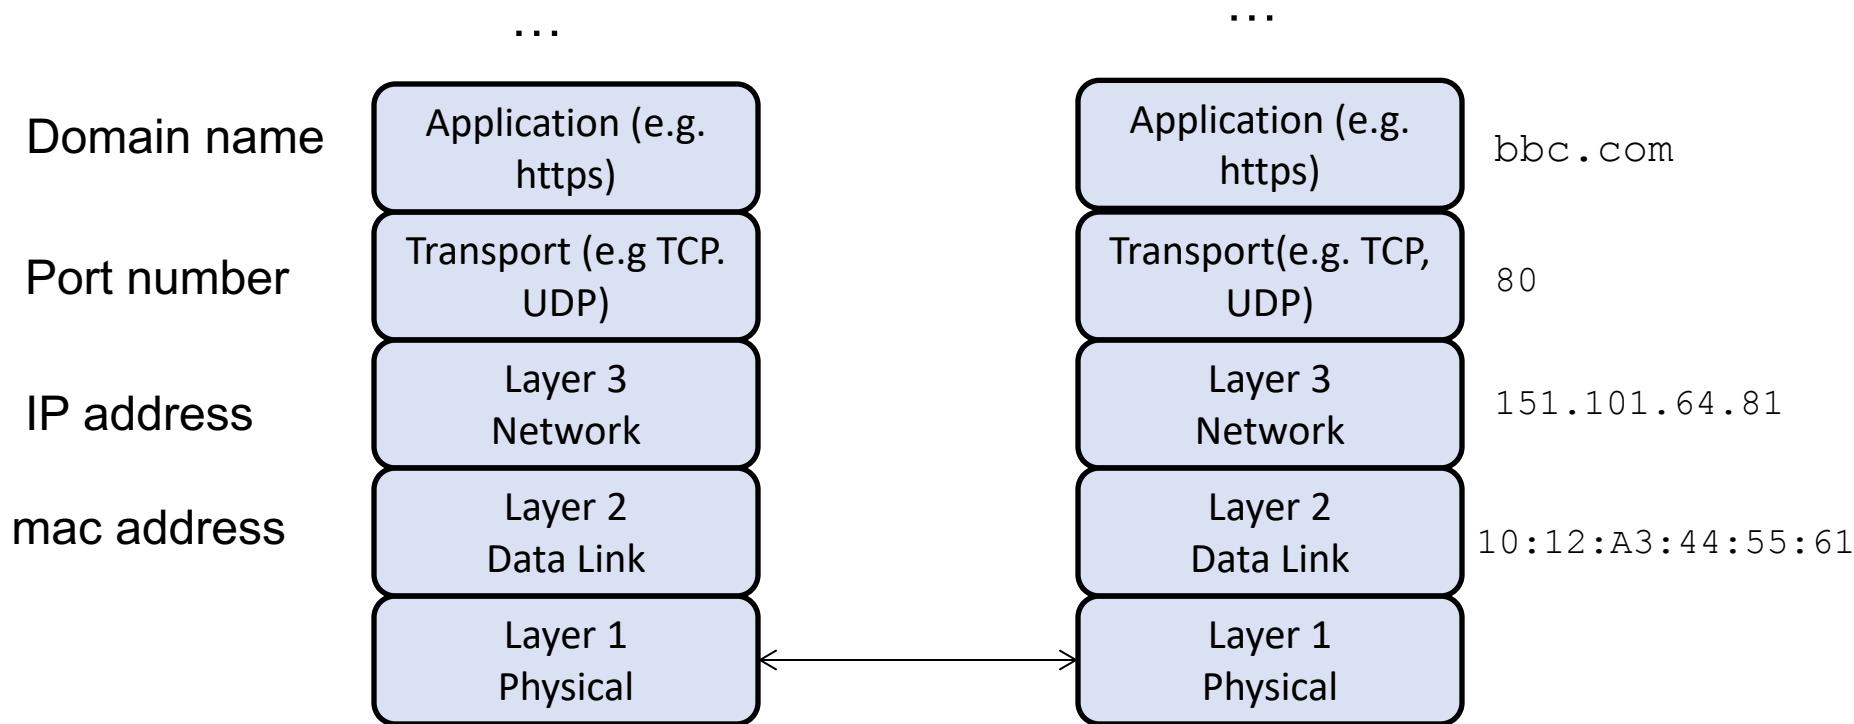

A Layer 3 services (called **handshake**) is designed as follow,

**Handshake** (A,B):  
(1) A → B: "hello"  
(2) A ← B: certificate of B.

The connection "A → B" is provided by Layer 2. The "virtual connection" at layer 2 sends the message "hello" from A to B in step (1), and sends the certificate in step (2).

Now, another entity in Layer 4 can use the layer 3's service **handshake**.

# Internet layers:

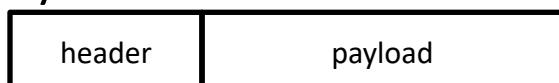

While the Open Systems Interconnection model (OSI model) gives 7 layers. In practice and this module, we are interested in the above layering.

# Naming

- A node in a network has different names in different layers.
- Four types of names are of particular concern in here.
  - Domain Name:                   bbc.com
  - Port Number:                   80
  - IP-address:                   151.101.64.81
  - mac-address:                   10:12:A3:44:55:61

# Datagram, Packet, Frame (PDU)

- When a layer-N service is invoked to send a message, the protocol in layer N might divide/merge the message into smaller units (i.e. the PDU).
  - In transport layer (layer 4), each portion is called a “datagram”.
  - In network layer (layer 3), it is called a “packet”.
  - In datalink layer (layer 2), it is called a “frame”.
- A packet/frame consists of two parts:
  - Header: this contains at least two pieces of information
    - The source (src) address, i.e. the sender’s address;
    - The destination (dest) address, i.e. the receiver’s address;
  - The payload: the data to be sent.

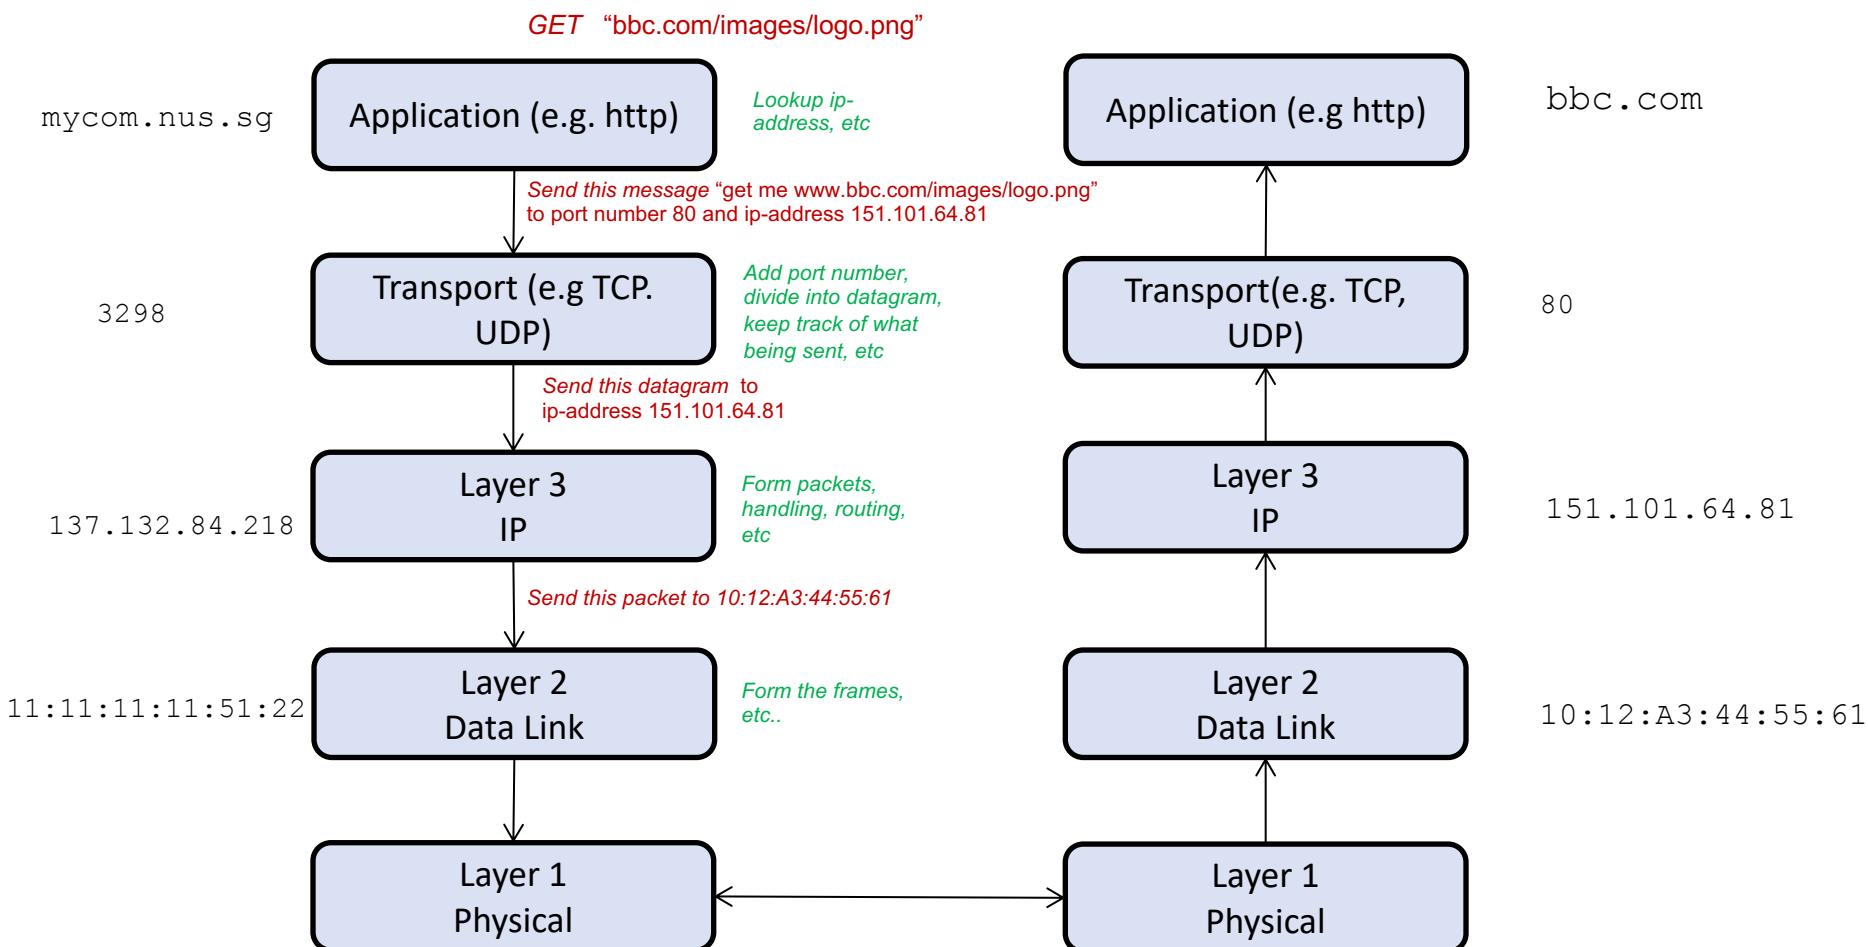

header: meta data

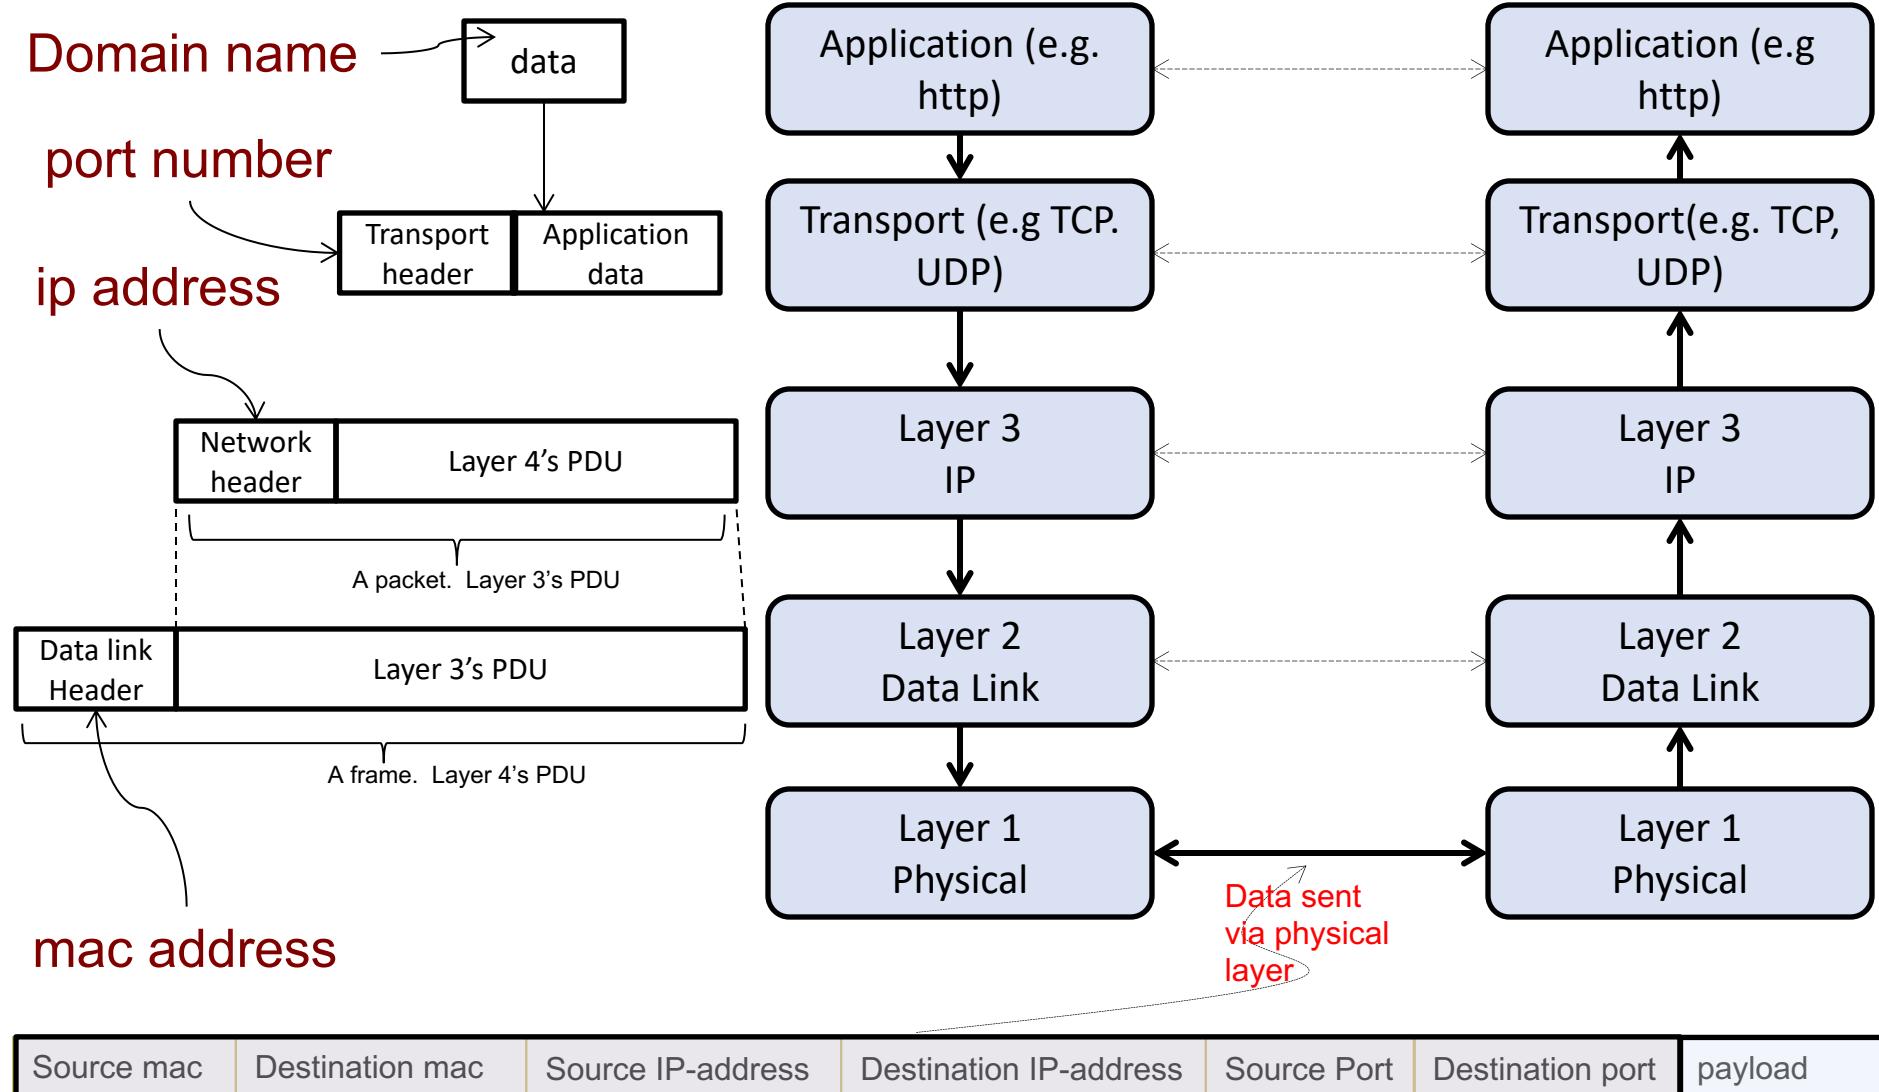

Payload: the message/information intend to be sent

# Data flow across the layers between two nodes

- When a node sends a message to another, the information flow “down” across the layers within the sender, and then “up” within the receiver.

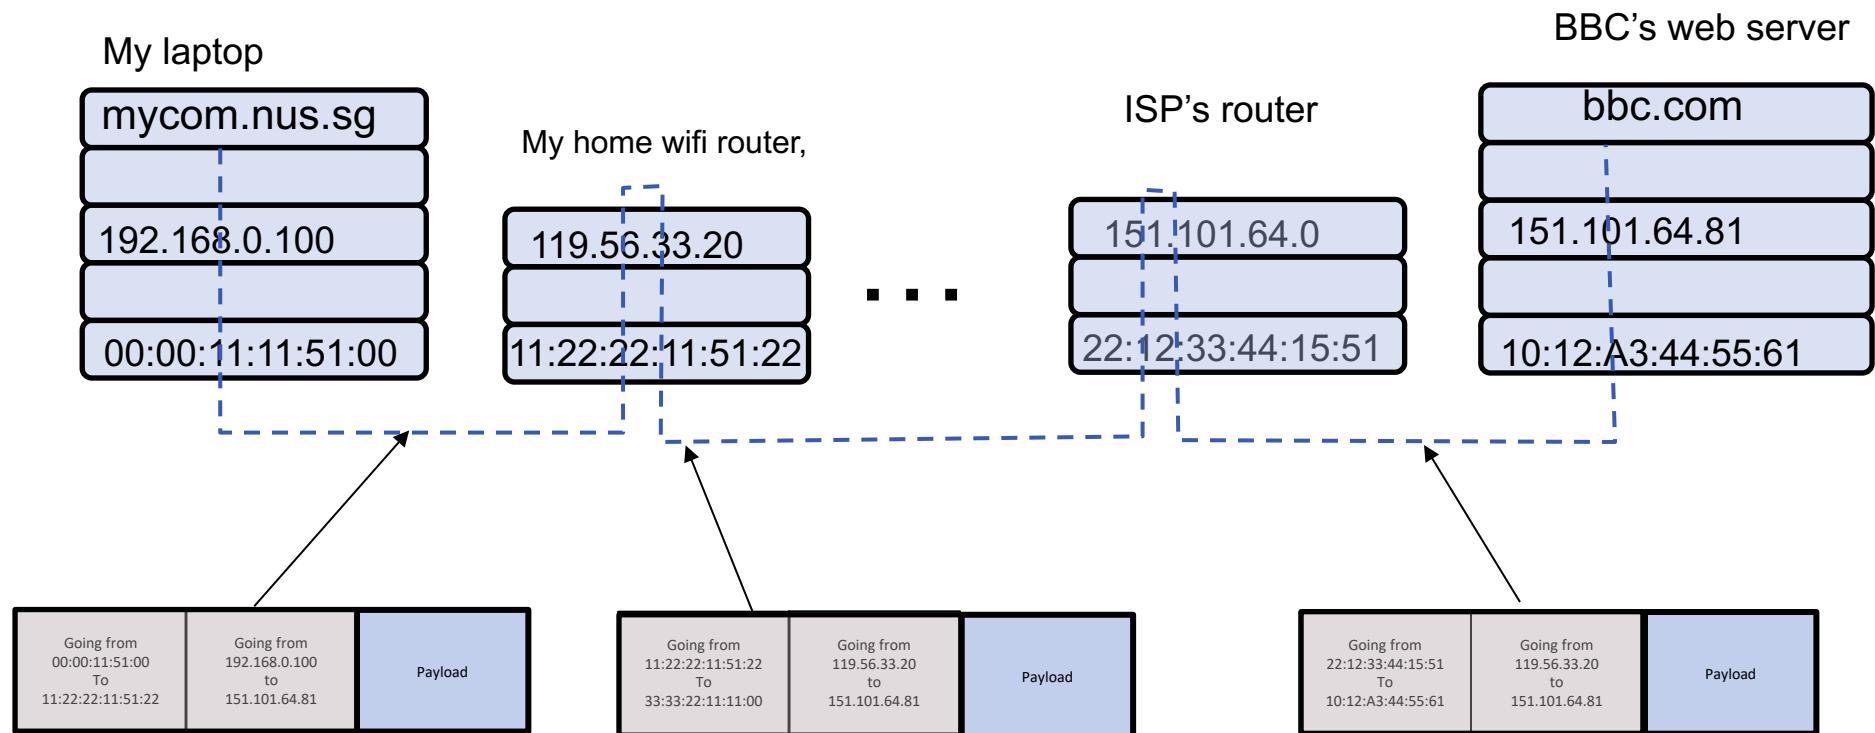

# Data flow across the layers between two nodes

# Multiple hops

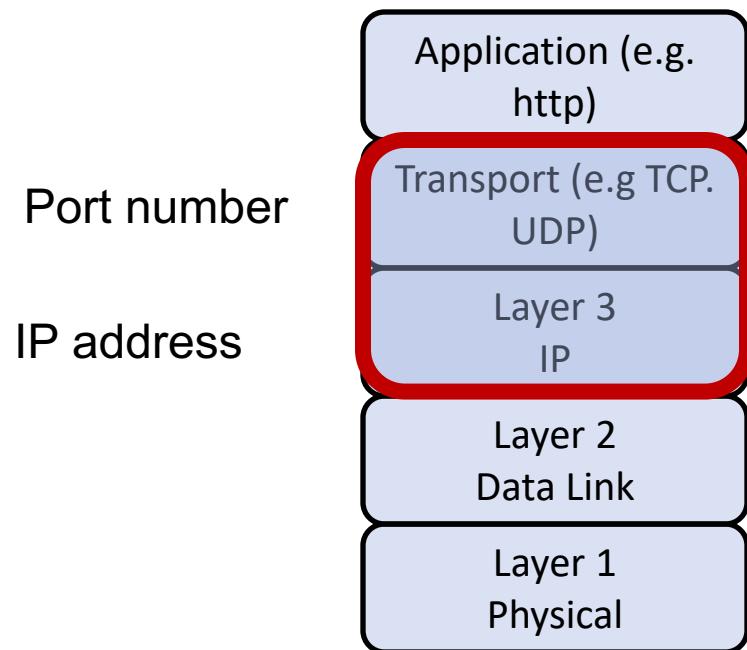

Data likely would go through multiple hops. Intermediate nodes could be owned by different semi-trusted third parties, e.g. Internet service provider (ISP), company's firewall. Intermediate nodes might change header information, translate the address etc, typically up to layer 3. Nonetheless, some intermediate nodes might change data in layer 4 and even application layer data.

# Challenges in Network Security

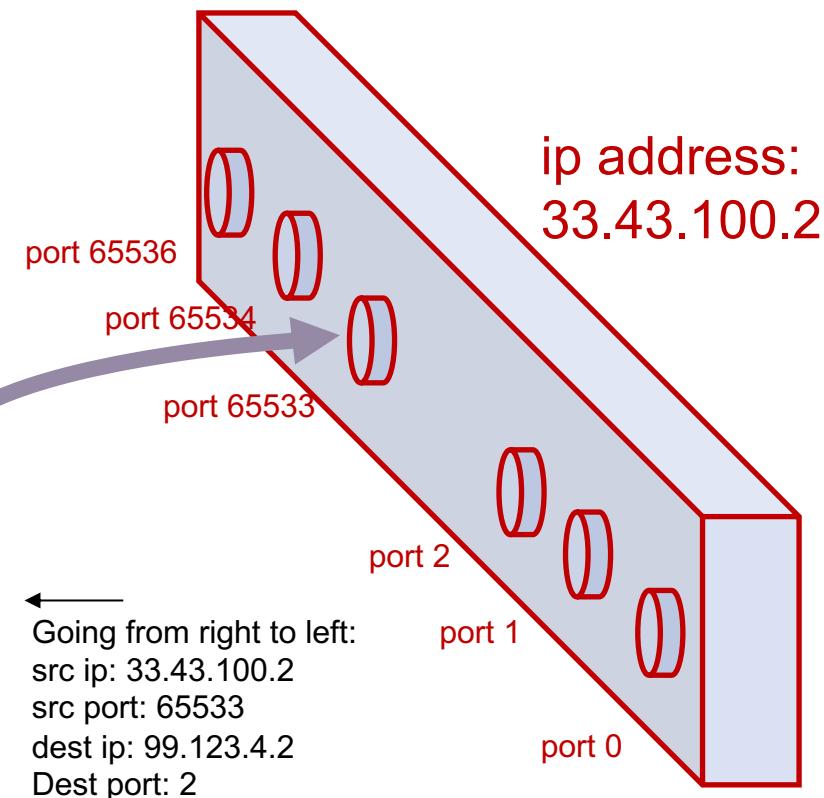

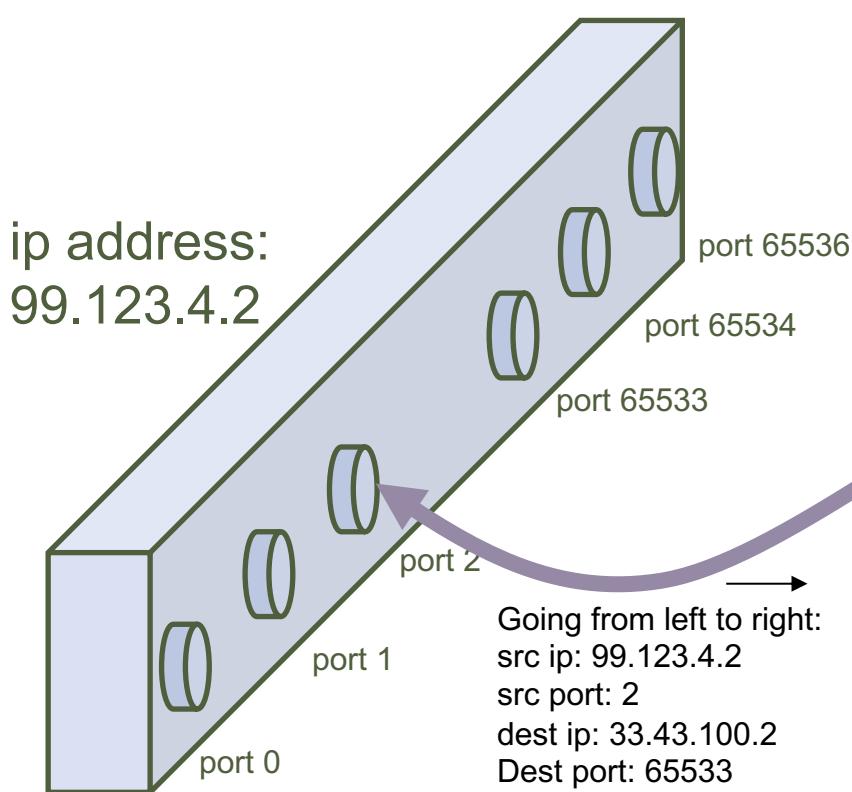

- (Complexity) Nodes are own by many different semi-trusted parties.
  - Intermediate node has access to both the header and the payload, and can modify (authenticity), read (confidentiality), drop (availability). An attacker at a certain layer can access all info in and below the layer.
- (Security Requirements) Many different security requirements.
  - In particular, availability can't be handled by crypto alone. Other requirements: anonymity, accountability, routing integrity, etc.
- (Legacy & security tradeoff) Initial design of many networking protocols did not consider intentional attacks.
  - For e.g., source ip-address in the IP header. Without additional protection mechanisms, a malicious sender can send packets with spoofed source ip-address.
  - For better performance and usability, many services do not employ strong protection mechanisms (e.g. network printer, DNS).
- (Management) There is a need to isolate and control information flow.

# Remarks on TCP/IP and UDP/IP

# Transport + IP layer

- Very often, the transport layer and IP layer are treated as one single layer. In this combined layer, the address of a communicating entity in a particular channel is an ***ip-address*** and a ***port***.
- Each node in the network has 65535 ports.
- A communication channel between two nodes is established by connecting a port in each node. In the e.g. between **99.123.4.2:2** and **33.43.100.2:65533**.

# UDP/IP

- If an application/program wants to invoke the UDP/IP protocol to send a message, the library call (depending on the programming languages) is typically of the form:

```
DatagramSend ( 2, "33.43.100.2", 65533, message)  
src ip is implicit and  
thus no need to specify      src port      dest ip      dest port
```

- The library call would construct an *IP datagram/packet*, and sends it using data-link layer protocol.

- There is limit on the size of message, at most ~65,000 bytes.
- The library call does not return a result indicating whether the destination has indeed received the packet. There is a possibility that the packet is lost! This is the property of UDP protocol. It is
  - *an unreliable, and*
  - *connectionless communication.*

# TCP/IP: *reliable* communication

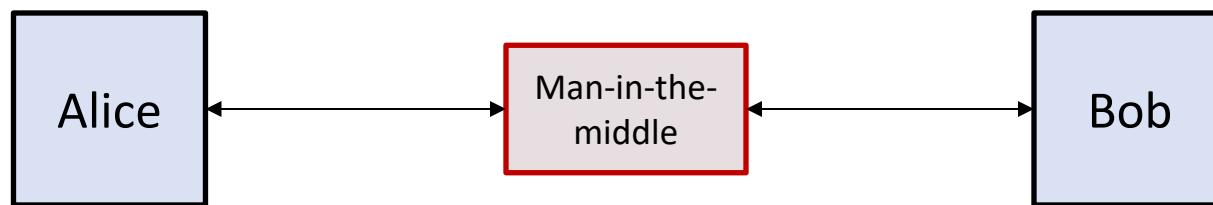

- In contrast, TCP/IP is *reliable*.
- An application/program would typically make the library calls (depending on programming languages) of the form and in the following order:
  - `P = open_connect (2, "33.43.100.2", 65533)`
  - `send (P, out_message)`
  - `read (P, in_message)`
  - `close_connection(P)`

*There could be multiple rounds of send/read.*
- `open_connect` would carry out some form of hand-shake protocol (known as TCP 3-way handshake) between the two nodes.
- `send` would construct *ip packets* of the following form and pass them to the datalink layer. In case the message is too long, multiple ip packets will be formed. The protocol also employs some mechanism of re-sending, re-ordering, acknowledgement to verify that the destination has indeed received the full message in the correct order.

src ip	dest ip	src port	dest port	message
--------	---------	----------	-----------	---------

# Reliability does not imply Security

- TCP/IP is reliable but not “secure”. Intermediate nodes along the communication route can still modify data in the header and payload.
- For example, a malicious intermediate node can
  - spoof an IP packet to inform one node to close the connection, while still communicating with the other node.
  - change information on the packets ordering, so that dest reconstruct a scrambled message.
- The intermediate nodes can act as a *man-in-the-middle* in the ip layer.

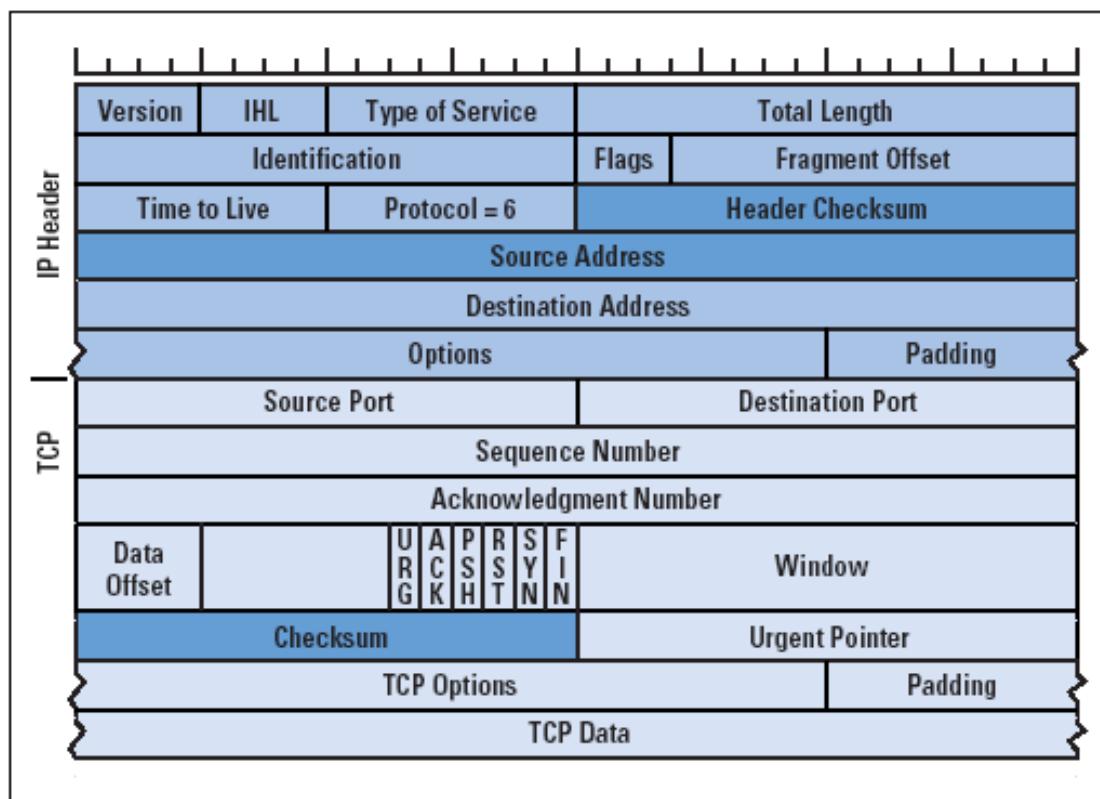

Optional

- Image from

<https://www.cisco.com/c/en/us/about/press/internet-protocol-journal/back-issues/table-contents-29/anatomy.html>

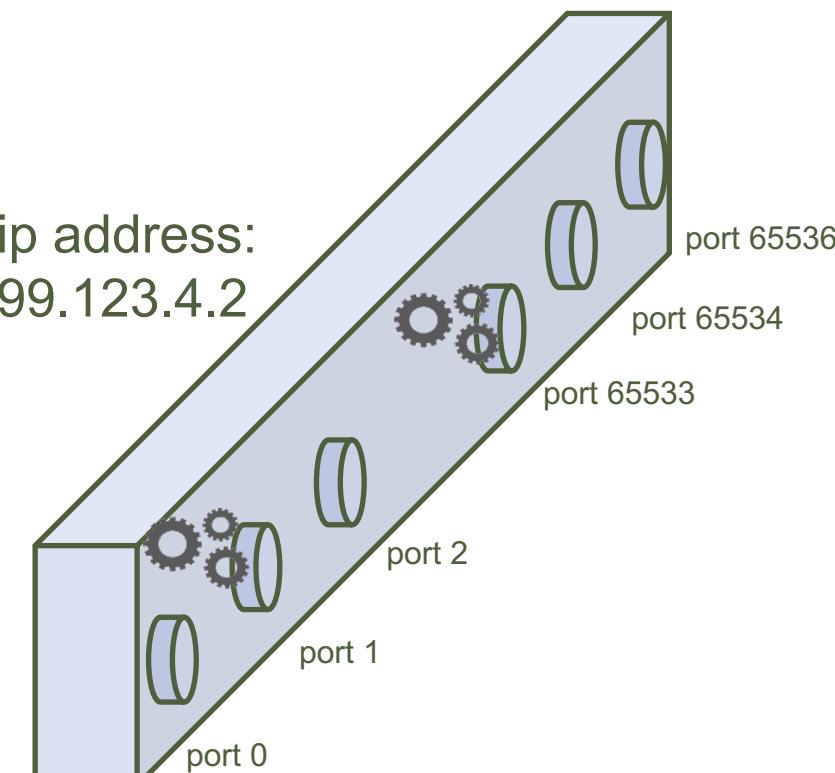

Figure 1: TCP/IP Header  
Fields Altered by NATs  
(Outgoing Packet)

# Listening Port

# What do we mean by “listening to a port”, “closed port”?

- We can imagine that behind certain ports (e.g. 1, 65533 in the e.g.), there are applications waiting to process data coming via the respective port. In such cases, we say that the node/process is “listening” to the port, and the port is a “listening port”. If the port is not listening, then it is a “closed port”.
- Data sent to a closed port will be dropped.

- There are security implications! We will revisit this in firewall design.
- Certain well-known services use widely agreed port. E.g. web server (HTTP) listen to 80, and hence the web server process is ready to process any request coming through 80.

## 5.2 Name resolution and attacks

- Each peer entity has a name. In a single node, at different layer, the name can be different.

- For a peer entity to use the virtual connection provided by layers below, it needs to find the corresponding name. E.g. finding the associated ip address for the domain name. **Method of finding the name is called “resolution” protocol.**
  - **DNS (Domain Name System):** resolution of Domain name to IP address
  - **ARP (Address Resolution Protocol):** resolution of IP address to mac address
- Many initial design of the resolution protocol didn't take security into account, and thus easy for attacker to manipulate the outcome.

- ARP attack targets at the association of ip-addr with mac-addr.
- DNS attack targets at the association of domain name with ip addr.

In this module, we only consider a basic type of DNS attack, and ARP poisoning.

**www.comp.nus.edu.sg** Domain name

## ~~ARP (Address Resolution Protocol)~~

**132.127.12.3** IP address

## ~~DNS (Domain Name System)~~

**01-02-03-04-05-06** mac address

# DNS (Domain Name System)

Given a domain name (e.g. [www.comp.nus.edu.sg](http://www.comp.nus.edu.sg)), its ip address can be found by looking up a locally stored table, or by querying a remote DNS server. The process is known as *resolution*. The client who initiates the query is called the *resolver*. If the address is found, we say that the domain name is *resolved*.

Demo:

```
$ nslookup www.comp.nus.edu.sg  
Server: 192.168.1.1  
Address: 192.168.1.1#53
```

Non-authoritative answer:

```
www.comp.nus.edu.sg canonical name =  
www0.comp.nus.edu.sg.
```

```
Name: www0.comp.nus.edu.sg
```

```
Address: 137.132.80.57
```

```
$
```

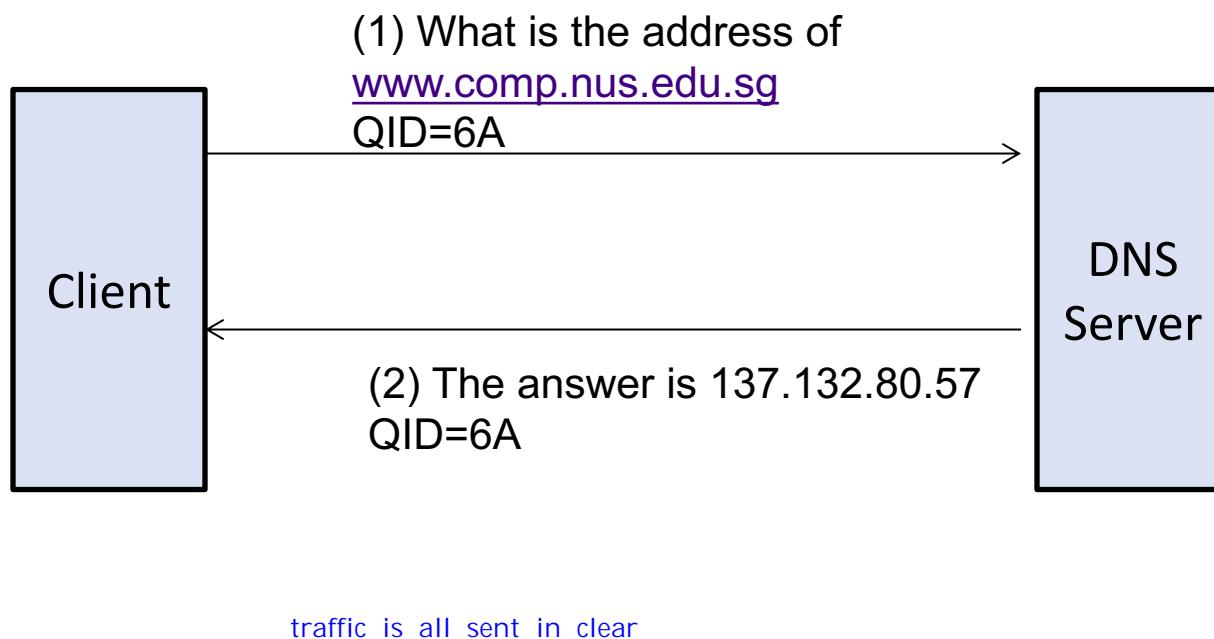

The domain name to lookup

Address of  
the DNS server

result of  
the query

# DNS query and answer

- Current DNS protocol does not protect (confidentiality and authenticity) the query nor the answer.

Some technical details:

- The query contains a 16-bit number, known as QID (query ID).
- The response from the server must also contain a QID.
- If the QID in the response doesn't match the QID in the query, the client rejects the answer. The design consideration of having QID probably is to match the query result to multiple queries sent out by the client. Nonetheless, this can be treated as a form of "light-weight" authentication.

# DNS spoofing: Attack Scenario

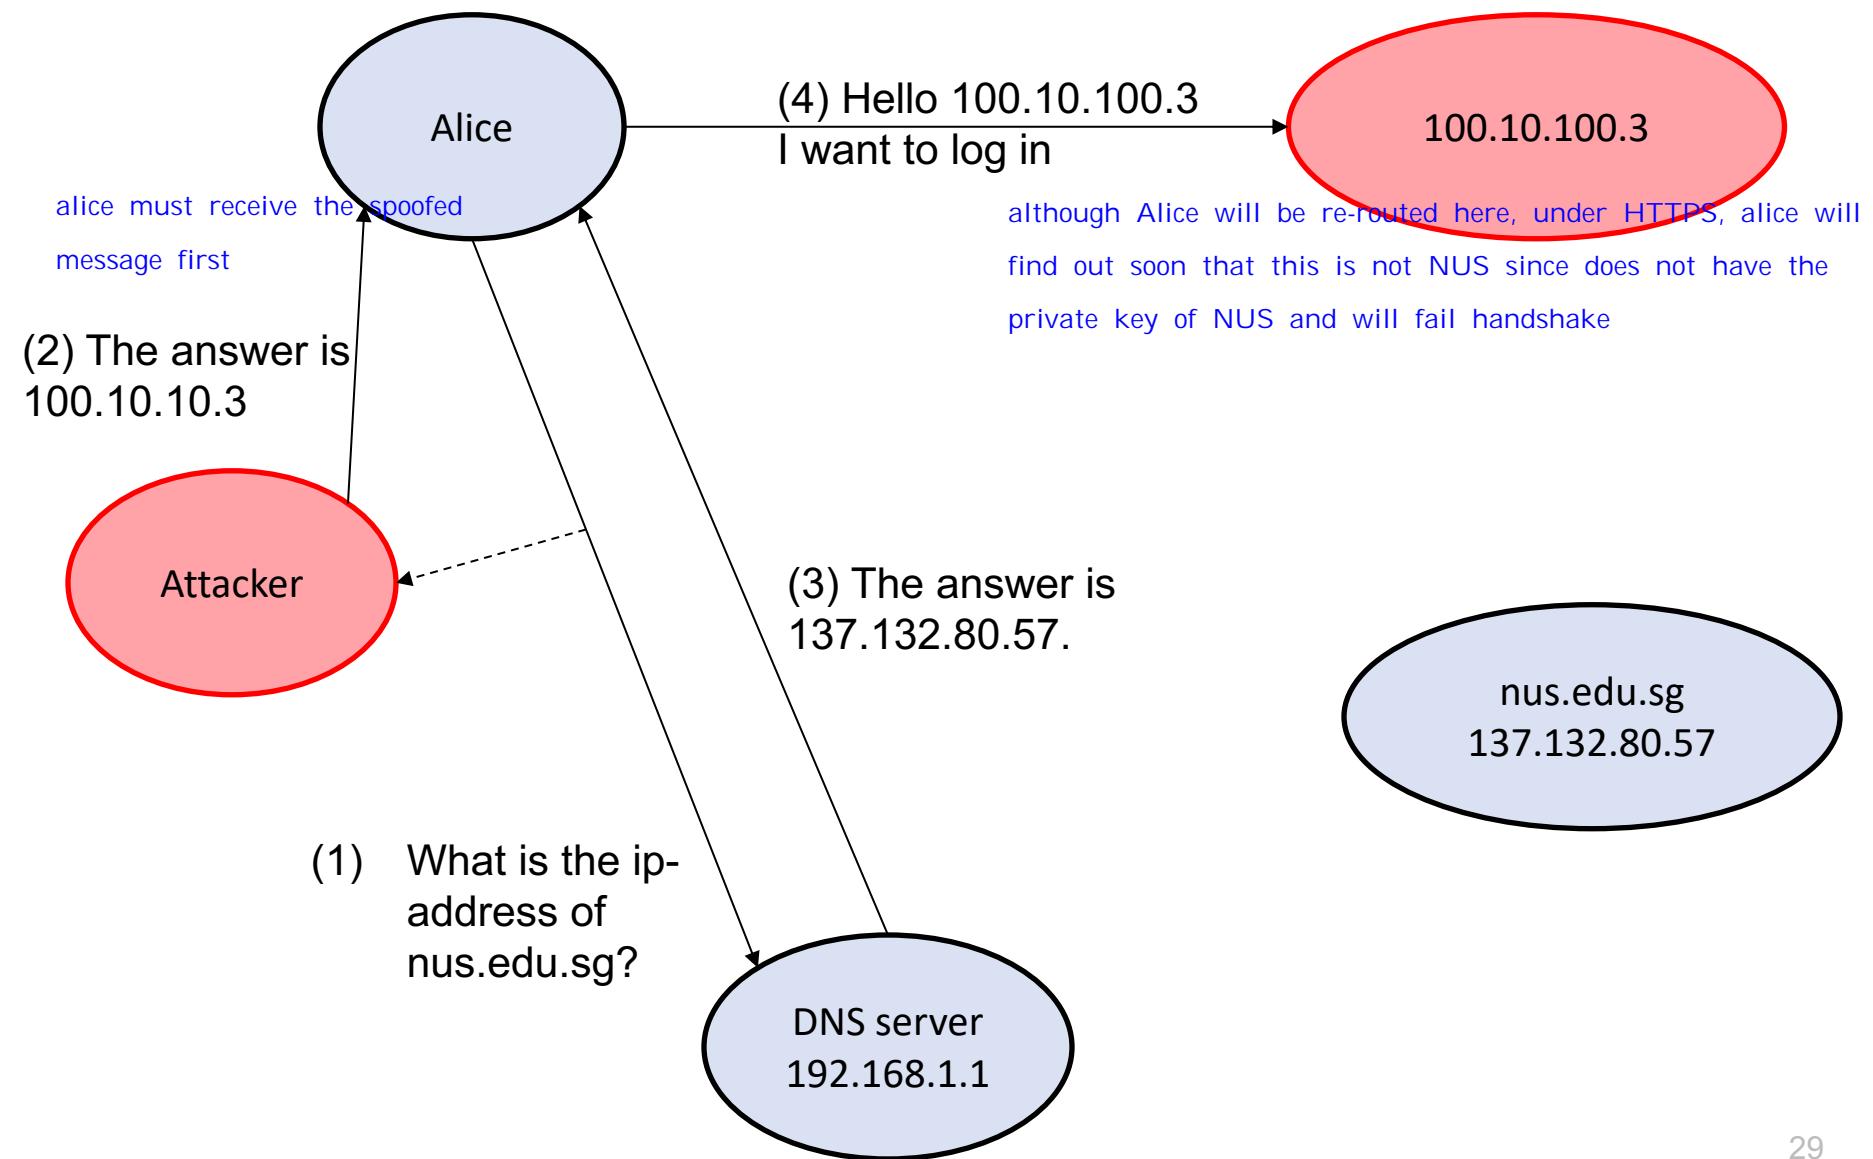

- Alice is using a café free wifi to surf the web.
- Alice wants to visit and login to [nus.edu.sg](http://nus.edu.sg)
- She types the domain name into the browser address bar.
- The browser makes a query to a DNS server to determine the ip address.  
(e.g. by executing nslookup)
- After the browser obtained the ip address, it connects to the ip address.

## Attack:

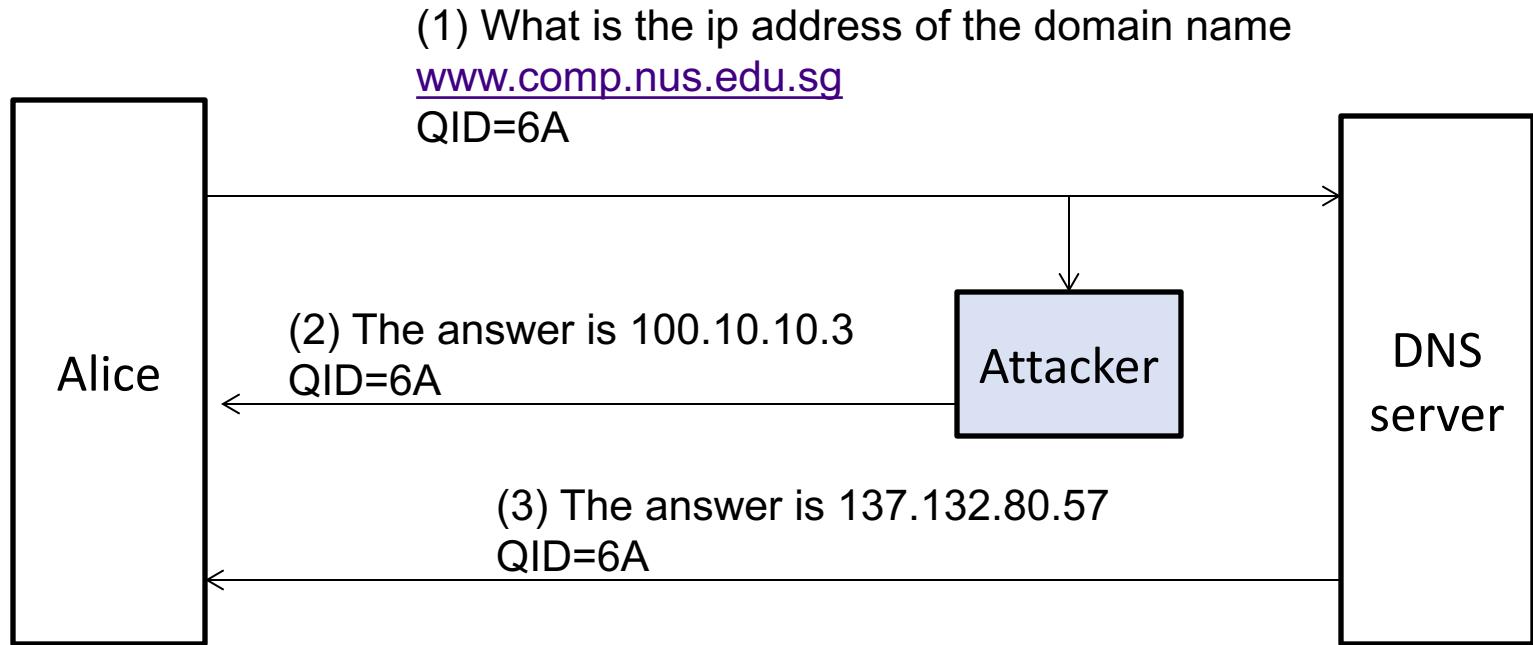

- We consider an attacker who is also in the café. Since the wifi is not protected, the attacker can
  - sniff data from the communication channel.
  - Inject spoofed data into the communication channel.

However, the attacker can't remove/modify data sent by Alice.  
(the attacker sits in the physical layer).

- Attacker owns a webserver at 100.10.10.3 which is a spoofed NUS website.

# The attack

Step (1) Alice asks for the address.

Step (2) Attacker sniffs and knows about it. Attacker quickly spoofs a reply with the same QID.

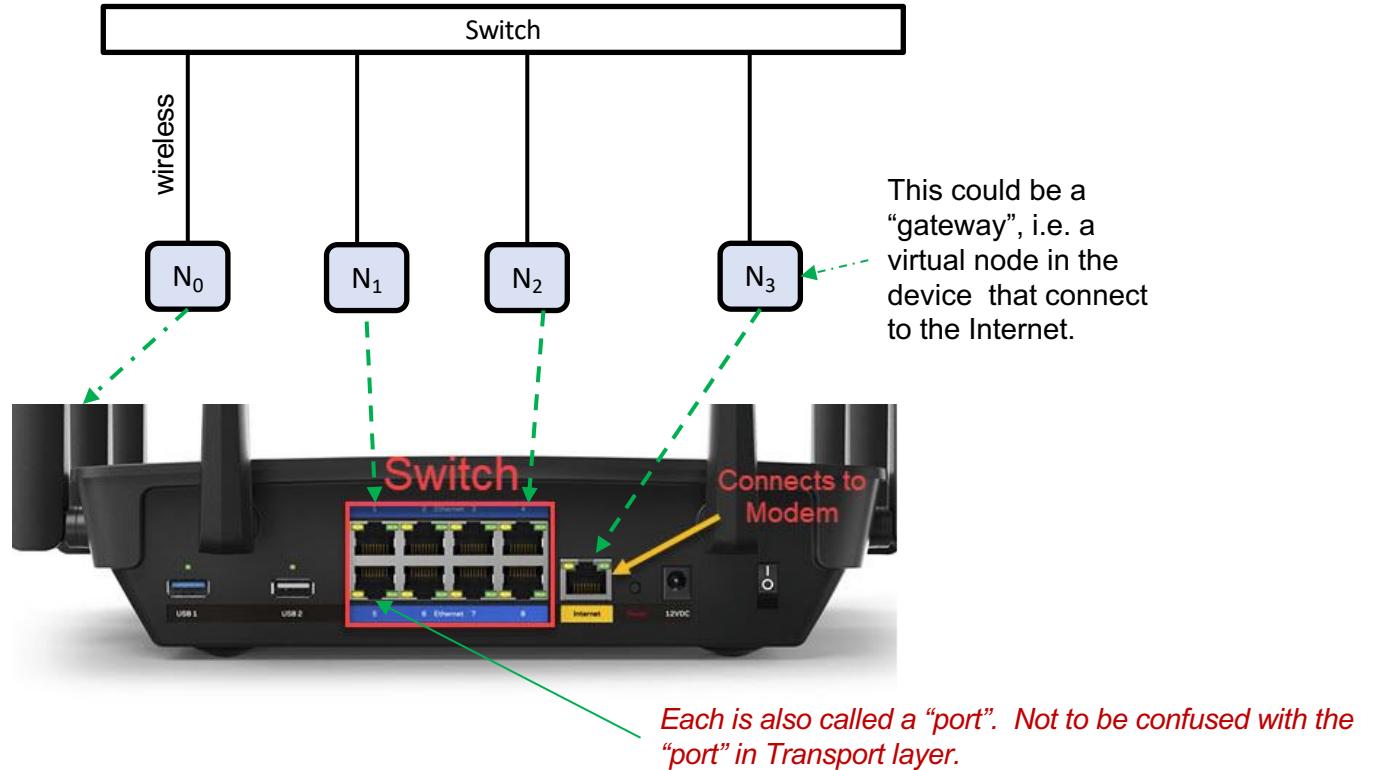

Step (3) DNS server also sends a reply. Since Attacker is closer to Alice, Attacker's reply likely to reach Alice first.

Alice takes the first reply as answer, and connect to 100.10.10.3

- DNS is an important component as it resolves the domain name. Hence, an DNS server can be a “single-point-of-failure” of the network.
- A denial of service (DOS) attacks on a web service, instead of directly attack the web server, could conduct DOS to the DNS server instead. When DNS server is downed, the web service is not longer reachable.
- E.g. see attack on wikiLeak (<http://www.independent.co.uk/life-style/gadgets-and-tech/news/twitter-down-is-it-not-working-wikileaks-ddos-us-election-japan-a7402081.html> and [PF6.5]pg 414, [Pf]page 485).

# Poisoning attack on ARP table

- A switch connects a few nodes. (Note that *switch* handles mac-addresses, *router* handles ip-addresses.)

- E.g. our home wifi “router”, although often called as a “router”, it also functions as a switch.

- The role of the switch is similar to the telephone switchboard shown earlier. It connects two “ports”.
- Switch doesn’t understand ip-addresses and doesn’t store ip-addresses. It connects ports based on mac-addresses.
- The switch keeps a table that associates the port to the mac-addresses.
- Resolution of ip-address to mac-address is done by the nodes (e.g. desktop, mobile phone). Each node keeps a table that associates ip-address to mac-addresses.
- The nodes update each other using some protocols, regarding info on the ip-addresses and mac addresses.
- ***ARP poisoning*** is an attack that modifies (aka “poisons”) the tables so as to gain Man-In-The-Middle access.

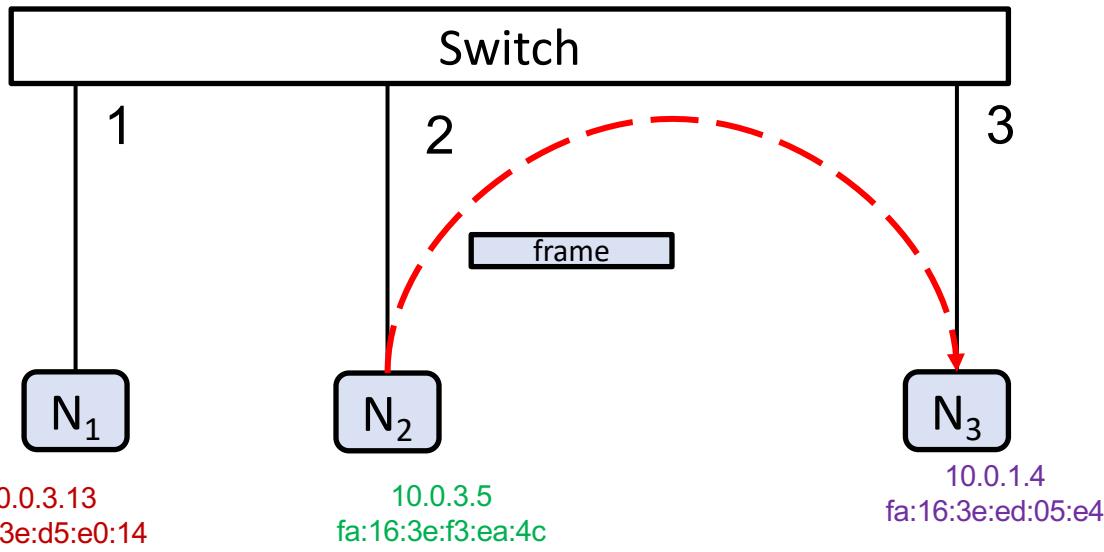

# When $N_2$ want to send to ip address 10.0.1.4

**T0**

Switch's port	Mac-address
1	fa:16:3e:d5:e0:14
2	fa:16:3e:f3:ea:4c
3	fa:16:3e:ed:05:e4

Under normal circumstances, these are carried out when  $N_2$  sends a packet to 10.0.1.4

1.  $N_2$  looks up the table **T2**. Resolve to fa:16:3e:ed:05:e4
2.  $N_2$  sends the frame to the switch, specifying destination fa:16:3e:ed:05:e4
3. Switch looks up the table **T0**, redirect the frame to port 3.

Ip-address	Mac-address
10.0.3.13	fa:16:3e:d5:e0:14
10.0.1.4	fa:16:3e:ed:05:e4

**T2**

Ip-address	Mac-address
10.0.3.13	fa:16:3e:d5:e0:14
10.0.3.5	fa:16:3e:f3:ea:4c

**T3**

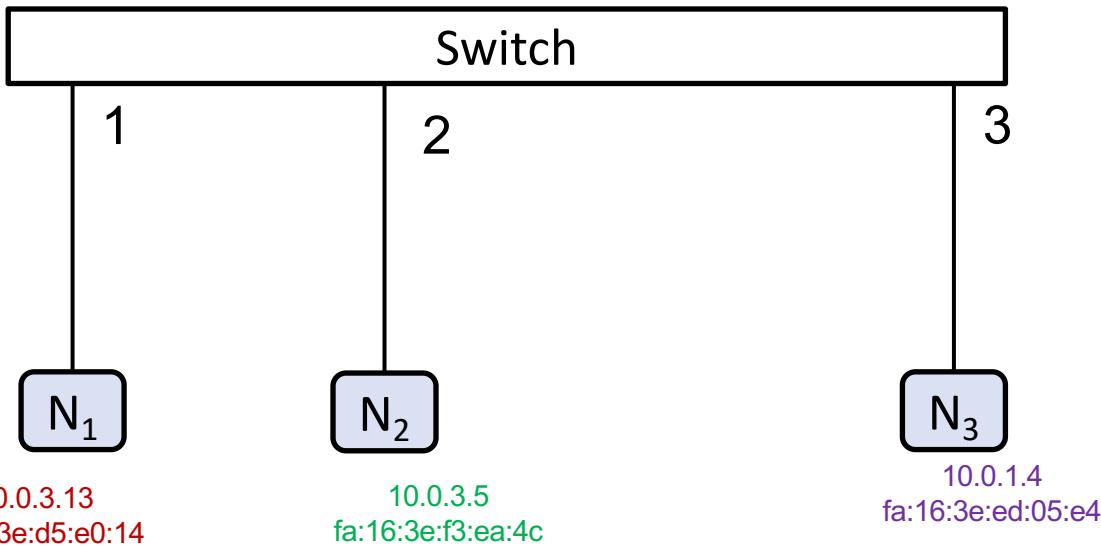

*Note:*

- $T0$  stored in switch.
- $T2$  stored in  $N_2$
- $T3$  stored in  $N_3$

# Attack: $N_1$ wants to be MITM between 10.0.3.5 and 10.0.1.4 $T_0$

Switch's port	Mac-address
1	fa:16:3e:d5:e0:14
2	fa:16:3e:f3:ea:4c
3	fa:16:3e:ed:05:e4

1.  $N_1$  informs  $N_2$  that mac address of 10.0.1.4 is fa:16:3e:d5:e0:14
2.  $N_1$  informs  $N_3$  that mac address of 10.0.3.5 is fa:16:3e:d5:e0:14

Ip-address	Mac-address
10.0.3.13	fa:16:3e:d5:e0:14
10.0.1.4	fa:16:3e:ed:05:e4

Ip-address	Mac-address
10.0.3.13	fa:16:3e:d5:e0:14
10.0.3.5	fa:16:3e:f3:ea:4c

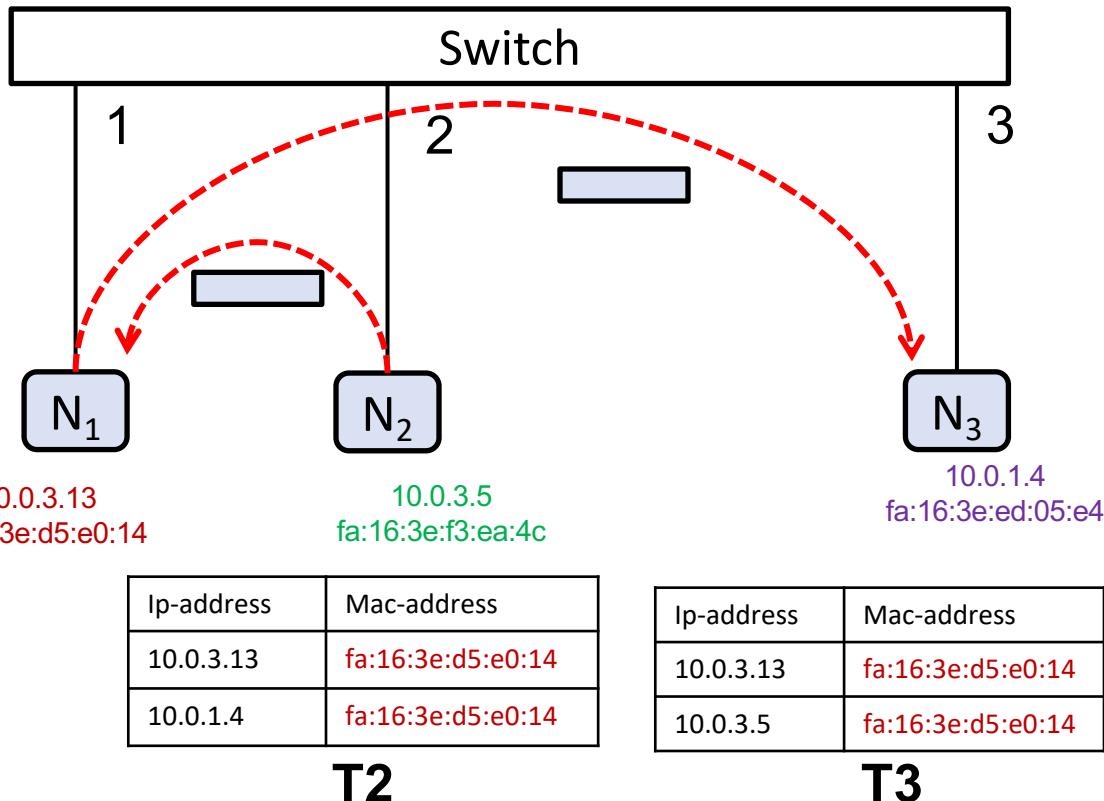

**T2**

**T3**

# Attack: N<sub>1</sub> wants to be MITM between 10.0.3.5 and 10.0.1.4 T<sub>0</sub>

Switch's port	Mac-address
1	fa:16:3e:d5:e0:14
2	fa:16:3e:f3:ea:4c
3	fa:16:3e:ed:05:e4

- After the tables are poisoned, all frames will be sent to N<sub>1</sub>.
- N<sub>1</sub> can relay the frames, or modify the frames before relaying.
- Hence, N<sub>1</sub> become the MITM in layer 2.

## 5.3 Denial of Service Attack

to mitigate is just to increase the size  
-like in cloud services is elastic, can expand size to handle incoming services as and when  
-or to see incoming packets and determine how to handle them based on determining their purpose, can drop or put on low priority

can use to disrupt a DNS service

DOS is an attack on availability.

**Availability:** The property of being accessible and usable upon demand by an authorized entity.

**Denial of service (DOS):** The prevention of authorized access to resources or the delaying of time-critical operations.

just to disrupt

Many successful DOS attacks simply flood the victims with overwhelming requests/data.

## Example of DOS attack

- Simply flood a web-server with http requests.

E.g. MyDoom worm which targeted SCO's website. Attacks starts on Feb 12, 2004.

- Sending large number of DNS requests to the DNS server.

For DOS to be effective, large number of attackers are required.  
(a single attacker can send requests only at a low rate).

When DOS is carried out by a large number of attackers, this is called ***DDOS: Distributed Denial of Service.***

# Reflection and Amplification attack

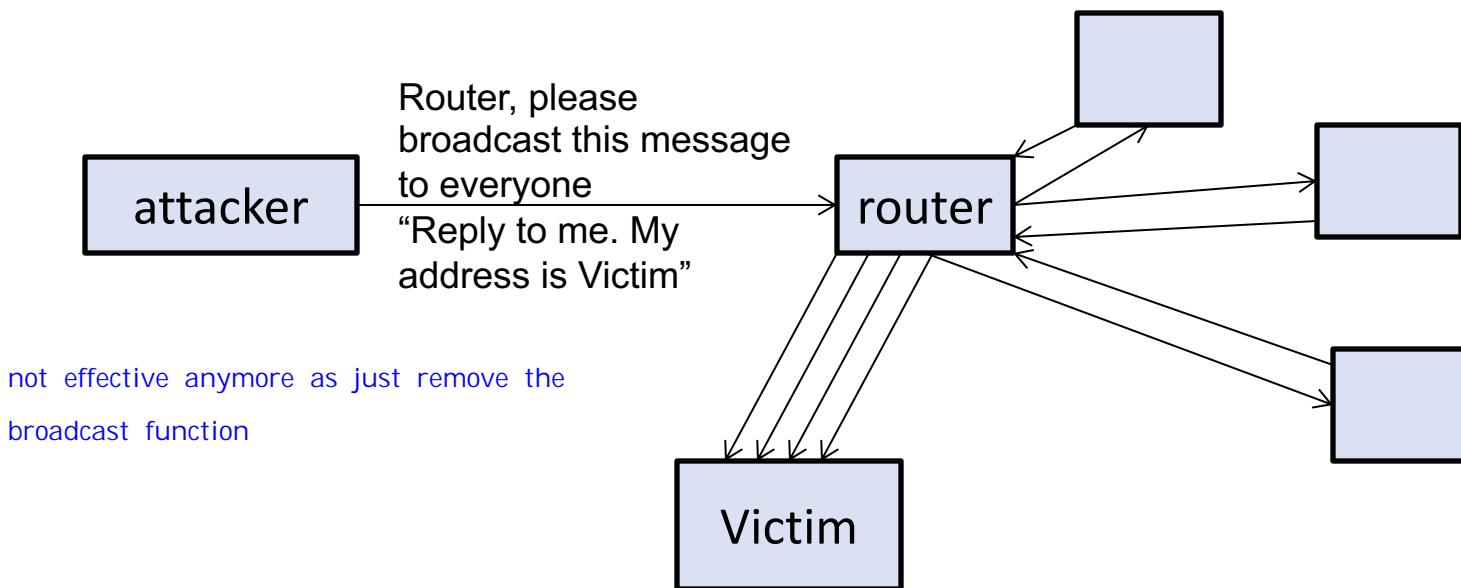

- Reflection attack is a type of DOS in which the attackers send requests to intermediate nodes, which in turn send overwhelming traffic to the victim.
- Indirect, and thus more difficult to trace.
- Very often, the reflected traffic could be amplified (a single request could trigger multiple responses from the intermediate nodes). Hence, these are also known as *Amplification attacks*.

# Eg of Reflection attacks: ICMP/Smurf flood

[PF] page 404

- Step 1. An attacker sends the request “ICMP PING” to a router, instructing the router to broadcast this request. The source ip-address of this request is spoofed with the victim ip address.
- Step 2. The router broadcasts this request.
- Step 3. Each entity who has received this request, replies to it by sending an “echo reply” to the source, which is the victim.

The victim's network is overwhelmed with the “echo reply”.

## Smurf flood preventive measure.

- This attack is no longer effective. Most router are now configured not to broadcast.
- To prevent attack, this measure simply disabled a feature that previously thought to be useful.

See IP broadcasting, [http://en.wikipedia.org/wiki/Broadcast\\_address](http://en.wikipedia.org/wiki/Broadcast_address)

# Other examples of Reflection attack

could be an amplification attack also, where the request is short and the reply is super long (which is chosen)

- DNS reflection attack.

“During a DNS amplification attack, the perpetrator sends out a DNS query with a forged IP address (the victim’s) to an open DNS resolver, prompting it to reply back to that address with a DNS response. With numerous fake queries being sent out, and with several DNS resolvers replying back simultaneously, the victim’s network can easily be overwhelmed by the sheer number of DNS responses.”

<https://security.stackexchange.com/questions/93820/dns-reflection-attack-vs-dns-amplification-attack>

UDP-based Amplification Attacks

Protocol	Bandwidth Amplification Factor
Memcache	50000
NTP	556.9
CharGen	358.8
DNS	up to 179 <small>[50]</small>
QOTD	140.3
Quake Network Protocol	63.9
BitTorrent	4.0 - 54.3 <small>[51]</small>
SSDP	30.8
Kad	16.3
SNMPv2	6.3
Steam Protocol	5.5
NetBIOS	3.8

What was the largest DDOS attacks  
(as of Nov 2018)?

Targeted at Github using Memcache on 5 March 2018. Generated data at a rate of 1.7 Terabits per second.

[https://en.wikipedia.org/wiki/Denial-of-service\\_attack](https://en.wikipedia.org/wiki/Denial-of-service_attack)

# Botnet

- A **bot** (aka *zombie*) is a compromised machine.
- A **botnet** (aka *zombie army*) is a large collection of connected bots, communicating via covert channels.
- A botnet has a command-and-control mechanism, and thus can be controlled by an individual to carry out DDOS.
- Possible usages of a botnet:
  - DDoS flooding, vulnerability scanning, anonymizing HTTP proxy, email address harvesting, cipher breaking!

**Question:** Why covert channels are used by a botnet?

this is to prevent the owner of the bot from finding out that it is being used.

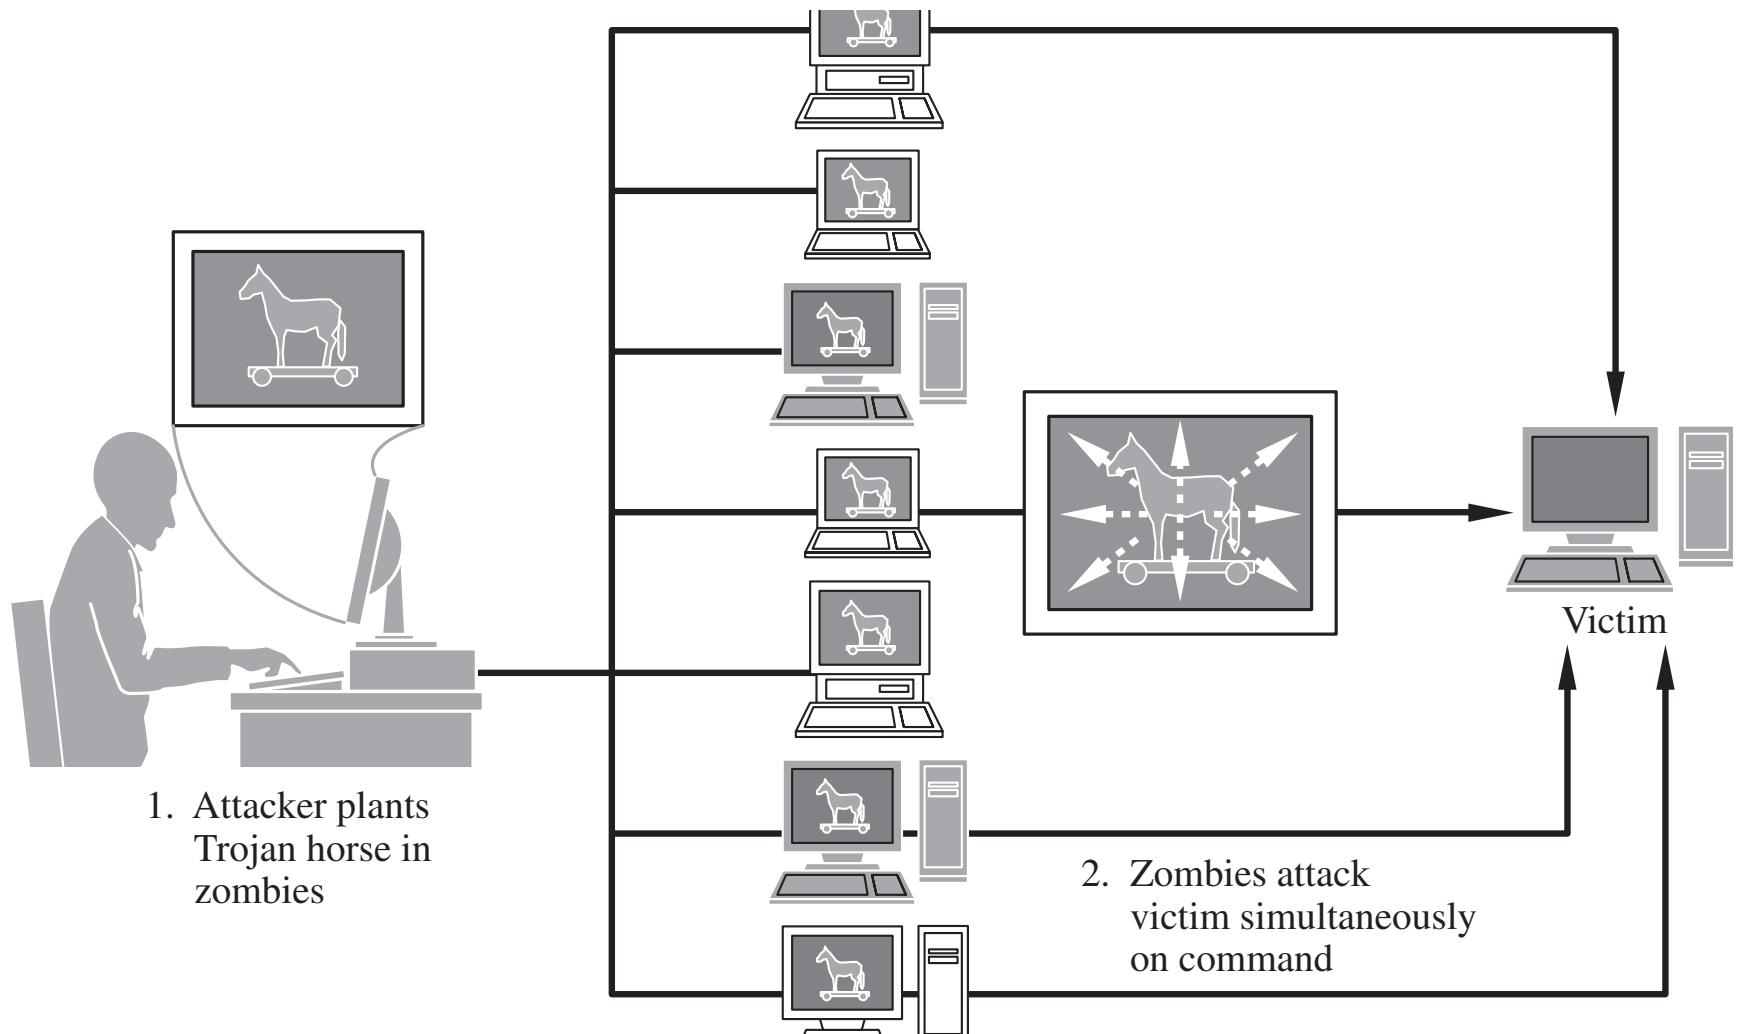

and also to make it harder to track

# Botnet

- Size of known botnets. <http://en.wikipedia.org/wiki/Botnet>

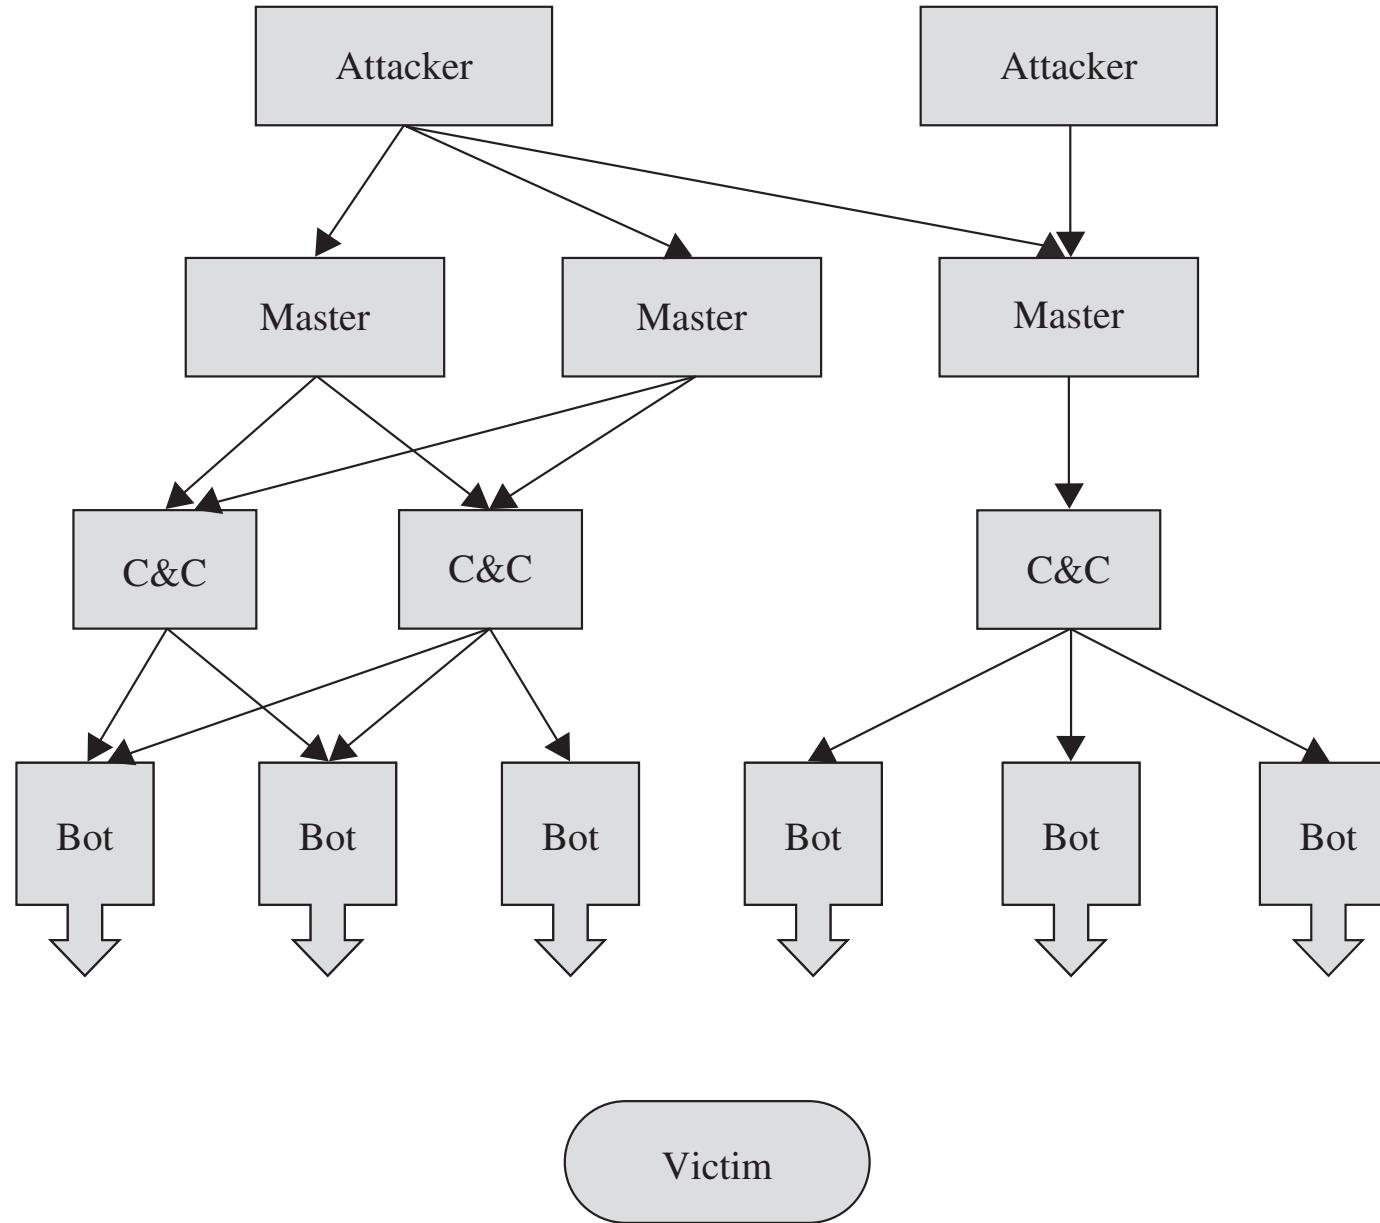

Date created	Date dismantled	Name	Estimated no. of bots	Spam capacity (bn/day)	Aliases
2009 (May)	November 2010 (not complete)	BredoLab	30,000,000 <sup>[51]</sup>	3.6	Oficla
2008 (around)	2009-Dec	Mariposa	12,000,000 <sup>[46]</sup>		
2008 (November)		Conficker	10,500,000+ <sup>[47]</sup>	10	DownUp, DownAndUp, DownAdUp, Kido
		Marina Botnet	6,215,000 <sup>[37]</sup>	92	Damon Briant, BOB.dc, Cotmonger, Hacktool.Spammer, Kraken
2010 (around)		TDL4	4,500,000 <sup>[56]</sup>		TDSS, Alureon
		Zeus	3,600,000 (US only) <sup>[57]</sup>		Zbot, PRG, Wsnpoem, Gorhax, Kneber
2011 or earlier	2015-02	Ramnit	3,000,000 <sup>[58]</sup>		
2007 (around)		Cutwail	1,500,000 <sup>[42]</sup>	74	Pandex, Mutant (related to: Wigton, Pushdo)

# Distributed Denial of Service (DDoS) using botnet

# Botnet

# DDoS Attacks trend

- There is a new trend of using “non-PC”, such as IoT devices, as bots in launching DDOS. A well-known example is the Mirai attack.
- List of well-known DDOS:
  - **4 March, 2018.** Victim Github. 1.7 tera bits per second (tpbs). Memcached. Record breaking.
  - **February 28, 2018.** Victim Github: 1.35 tbps. Memcached. Record breaking.
  - **October, 2016.** Using **Mirai to coordinate a botnet of IoT devices.** A series of attacks. Victim Dyn (a DNS service providers), French web host OVH (~1 tpbs).
  - **March 2015,** Victim Github. Believed to be originated from China. Javascript injection by “Great Firewall”.
  - **2013,** Victim Spamhaus. 0.3 tpbs. Record breaking. See <https://blog.cloudflare.com/the-ddos-that-almost-broke-the-internet/>
  - **27 April, 2007,** Victim Estonia’s government services. Believe to be politically motivated (state sponsored attack?)
  - **January, 2004.** Mydoom. Infected machines sent https requests to the victim, SCO’s websites `www.sco.com`. Spread infection by email. Estimated to generate 1 in every 5 emails at its peak.

## **5.4 Useful tools**

# Wireshark (packets analyzer)

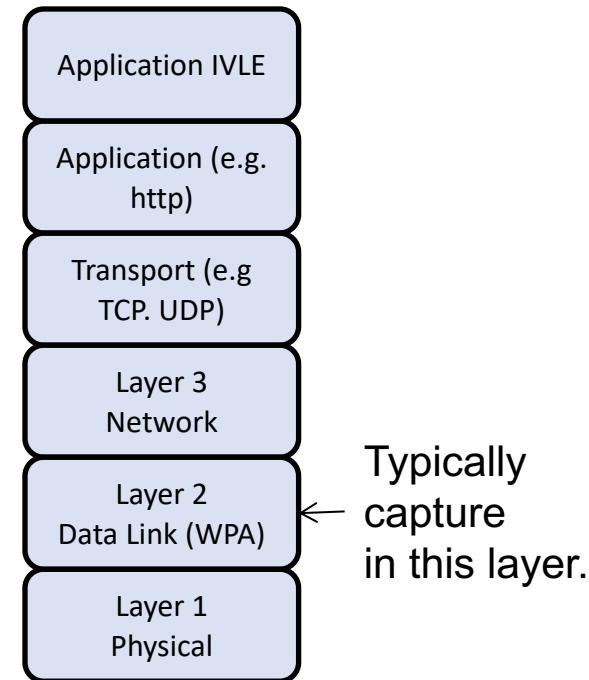

usually capture at the connection of the network card

Wireshark: a free open-sourced packets analyzer.

<https://www.wireshark.org/>

Exactly what does wireshark capture?

- Wireshark listens to “interactions” between the OS and the network card driver. (In other words, it is a MITM between OS and network card).
- Hence, header added by the network card, or modification made by the network card, may not be captured by Wireshark. This depends on the OS and the hardware.
- see the following FAQ for more info.  
<https://ask.wireshark.org/questions/22956/where-exactly-wireshark-does-captures-packets>

(demo: Wireshark)

# Useful Tools: Nmap (port scanning)

- Why port scanning?
- There are multiple processes in running in a server. When the server receives a packet, base on the port number, it will decide which process handle that packet. So, by saying that a process/service is “*listening*” to a particular *port*, we mean that the process is running and ready to handle arriving packets with that particular port number.
- When a port is “*open*”, there exist such a process running in the server. When a port is “*closed*”, no process is listening to that port.
- If a port is “*closed*”, attacker is unable to feed malicious data to that port.
- see  
[https://en.wikipedia.org/wiki/List\\_of\\_TCP\\_and\\_UDP\\_port\\_numbers#Well-known\\_ports](https://en.wikipedia.org/wiki/List_of_TCP_and_UDP_port_numbers#Well-known_ports) for well-known port number.

- Port scanning: The process of determining which ports are open in a network.
- Port scanner: A tool for port scanning. E.g. Nmap.
- Port scanner is a useful tool for attacker, and network administrator to scan for vulnerabilities.
- Is port scanning illegal?

(Read if you want to use it) <https://nmap.org/book/legal-issues.html>

(demo: Nmap)

# Nmap scan report on my desktop.

```
> nmap -v -p 1-65535 -sV -O -sS -T4 172.26.
```

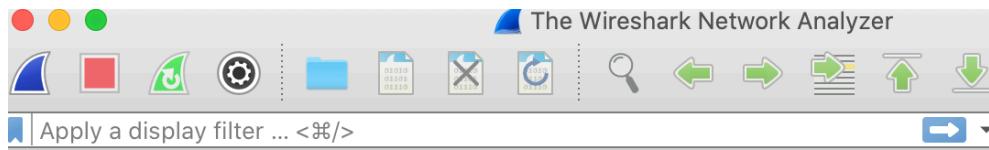

```
Starting Nmap 7.60 ( https://nmap.org ) at 2019-03-13 16:31 +08
NSE: Loaded 42 scripts for scanning.

# Wireshark Demo

# (1) Choose the “network interface”

(2) Set a capture filter if required.  
e.g simply leave it empty or “tcp”

This interface ip-address  
Is 192.168.50.183.

Its mac address  
(not shown in this screenshot)  
Is 78:4f:43:8b:47:aa

## Learn

[User's Guide](#) · [Wiki](#) · [Questions and Answers](#) · [Mailing Lists](#)

You are running Wireshark 2.2.6 (v2.2.6-0-g32dac6a).

Ready to load or capture

No Packets

(3) Too many info. Use the display filter to select what to see. Note the difference between display and capture filter.

(4) Click here to see various options for display filter.

We can use nslookup to find out more about an ipaddress.

(the is called reverser DNS lookup where find the domain name from ip-address.) We can also find the geolocation by using some services from the web. Does not always work.

## **5.5 Protection: Securing the communication channel using cryptography**

In the past few lectures, we have illustrated that cryptography techniques can be deployed to achieve confidentiality (encryption) and authenticity (mac, PKI, strong authentication) over a public communication channel, even if the adversary can sniff & spoof data.

There are many security protocols achieving that, but operates at different “layers”.

- The well-known TLS/SSL, WPA, IPSEC protect different layers.

# Remark on Layering

Very often, when referring to a security protocol, we indicate the “layer” the protocol targets to protect. (complication: some protections span across multiple layers, or do not provide full protection of the targeted layer.)

When analyzing an attack, it is also insightful to figure out at what layer the attacker resides. (complication: likewise, some attacks span across multiple layers. In such situations, trying hard to pin-point the layer could sometime be very confusing ).

A security protocol that protects layer k, would protect information in that layer and above.

Hence, if an attacker resides at layer 1, and there is a security protocol that protect layer 3, then information generated in layer 3 and above will be protected, but information generated in layer 2 would not be protected by the security protocol

# 1. SSL/TLS

- The SSL/TLS sit on top of Transport layer.
- We can imagine that, when an application (say browser or email agent) wants to send data to the other end point, it first passes the data and the address (ip address) to SSL/TLS. Next SSL/TLS first “protects” the data using encryption (confidentiality) and mac (authenticity), and then instructs the transport layer to send the protected data.

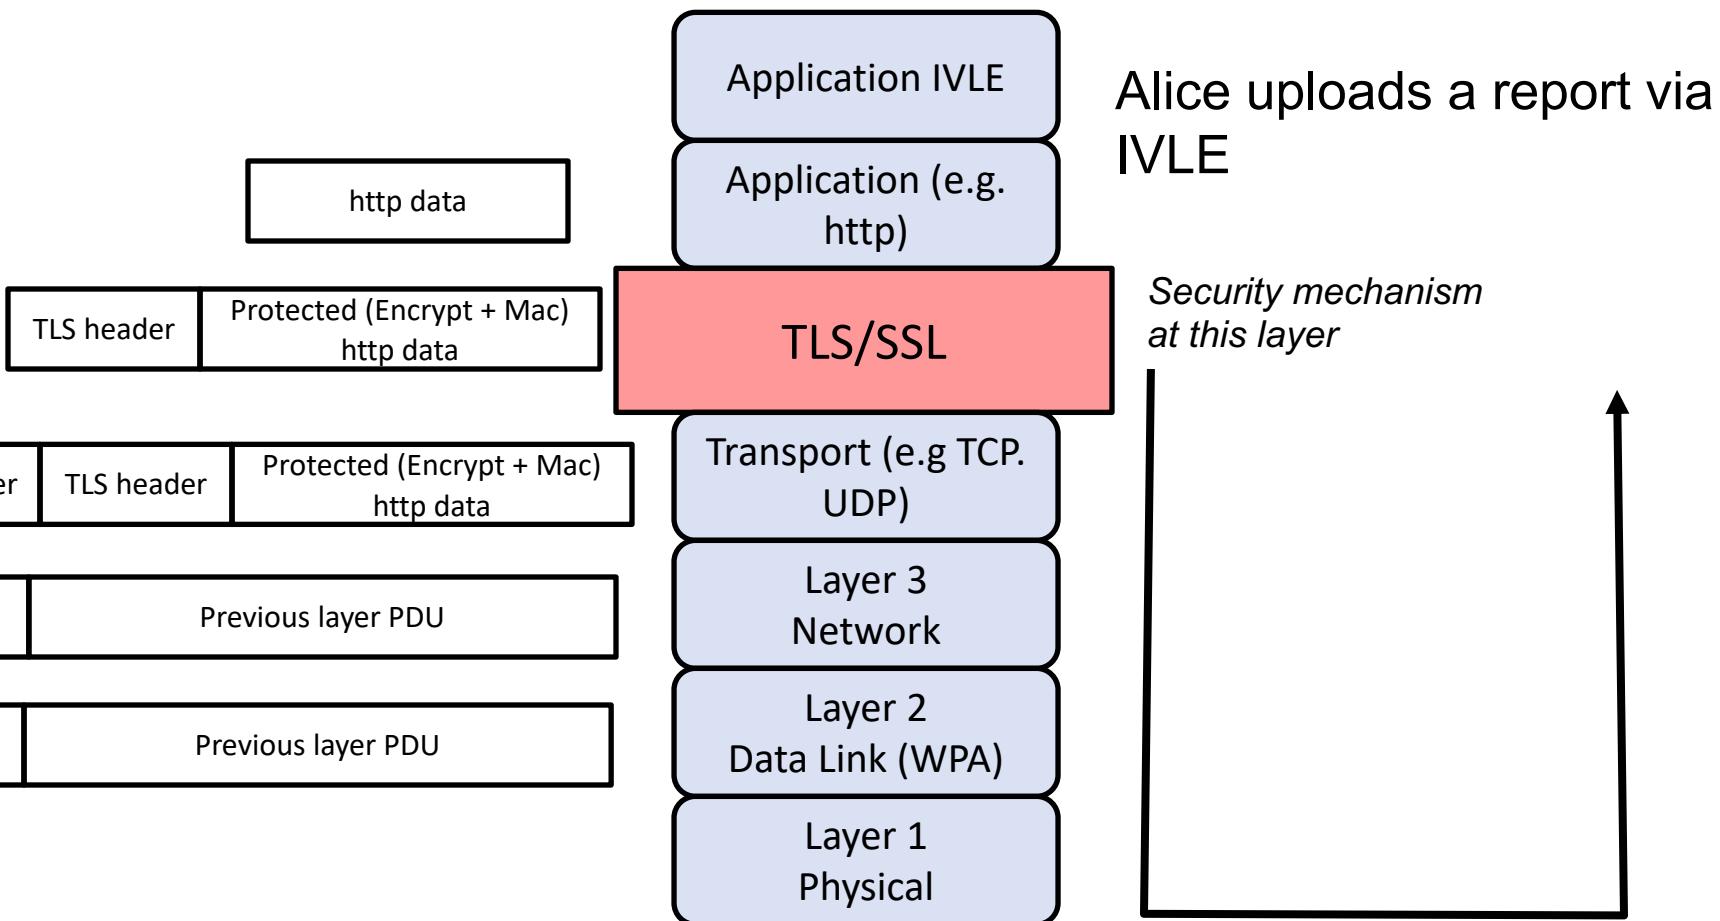

- E.g. Alice using IVLE to upload a report a.pdf to the IVLE server. Note that IVLE uses https, which in turn uses SSL/TLS.

Alice's machine carries the following:

1. The “IVLE” application passes the file a.pdf to https, and then to TLS.
2. TLS protects the data by encryption and mac.
3. TLS passes the protected data to the transport layer.

IVLE's server carries out the following:

1. The transport layer passes the protected data to TLS.
2. TLS decrypt the data and verify the mac for integrity.
3. TLS passes the decrypted data to IVLE's application.

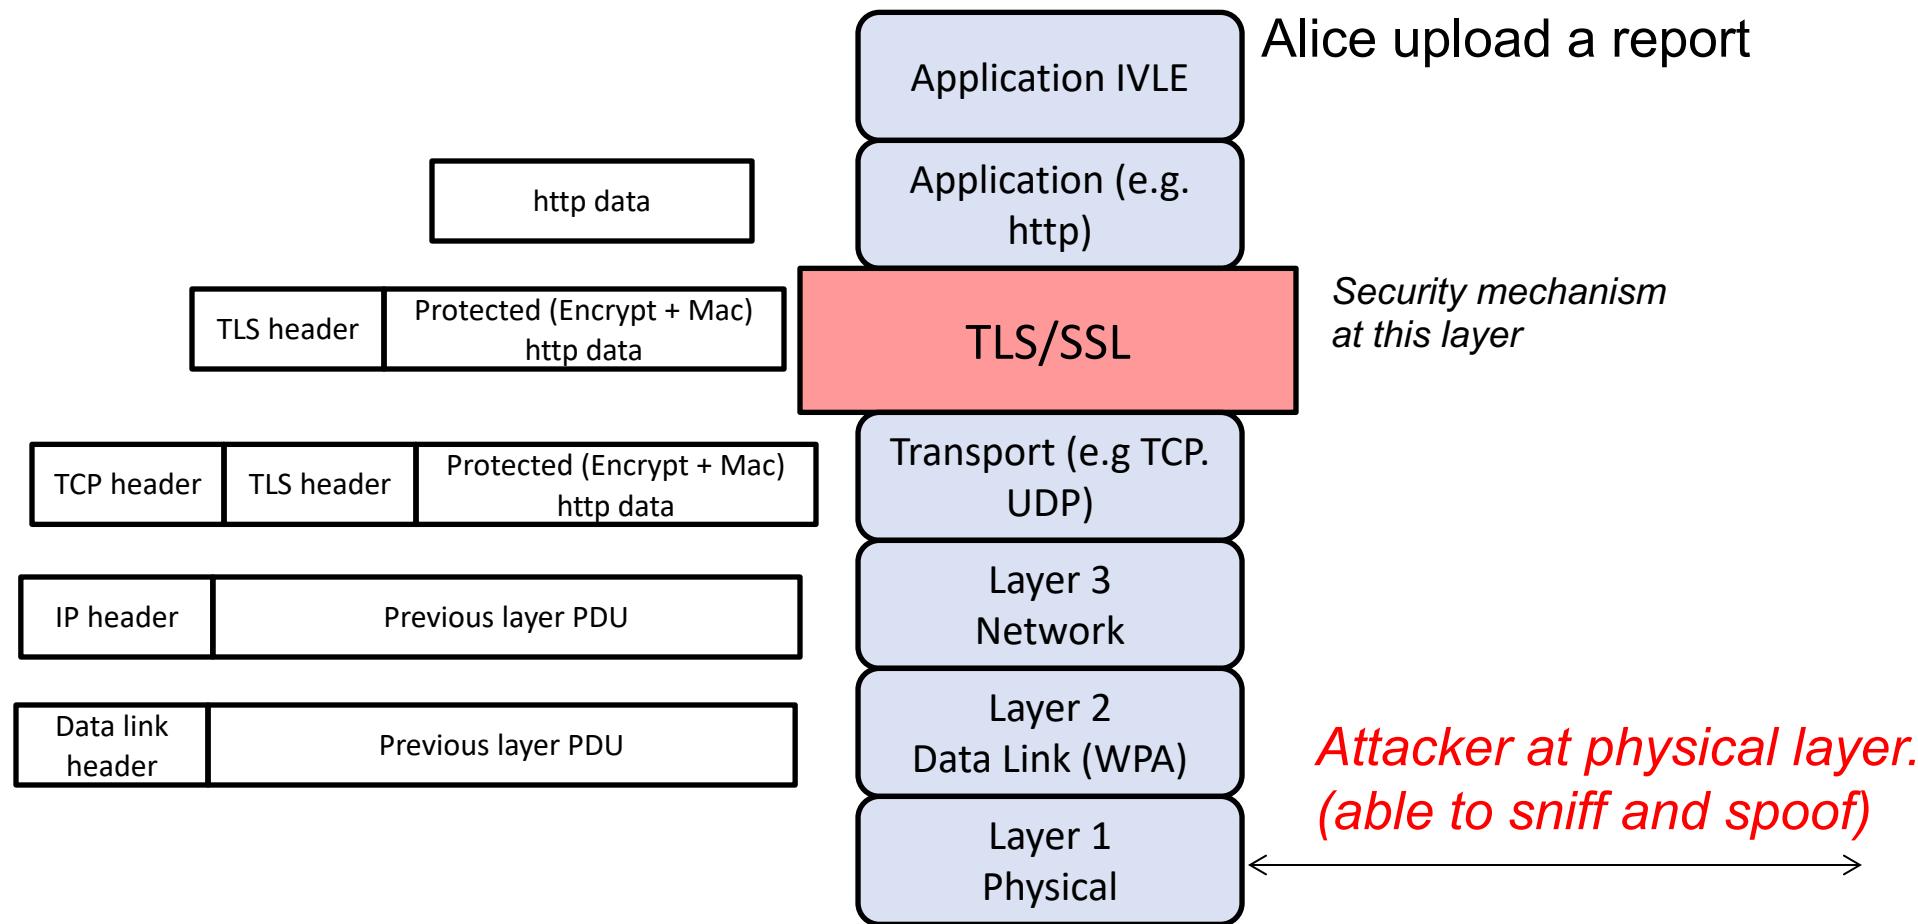

The receiver end-point decrypts the received data at the corresponding layer.

# Scenario 1

- Suppose that there is an attacker in the physical layer who can sniff and spoof message at that layer (i.e. MITM in the physical layer). For example, Alice uploading her report in a cafe using free wifi (without WPA protection). Hence anyone in the café has access to the physical layer and thus can sniff and spoof messages in that layer.
- Question: Can the attacker learn
  1. Alice's report? no, because do not have the private key of Luminus
  2. The fact that Alice is visiting IVLE website (i.e. can the attacker learn the ip-address)?

yes, because that those headers are not encrypted

# Attacker at physical layer.

## Scenario 2

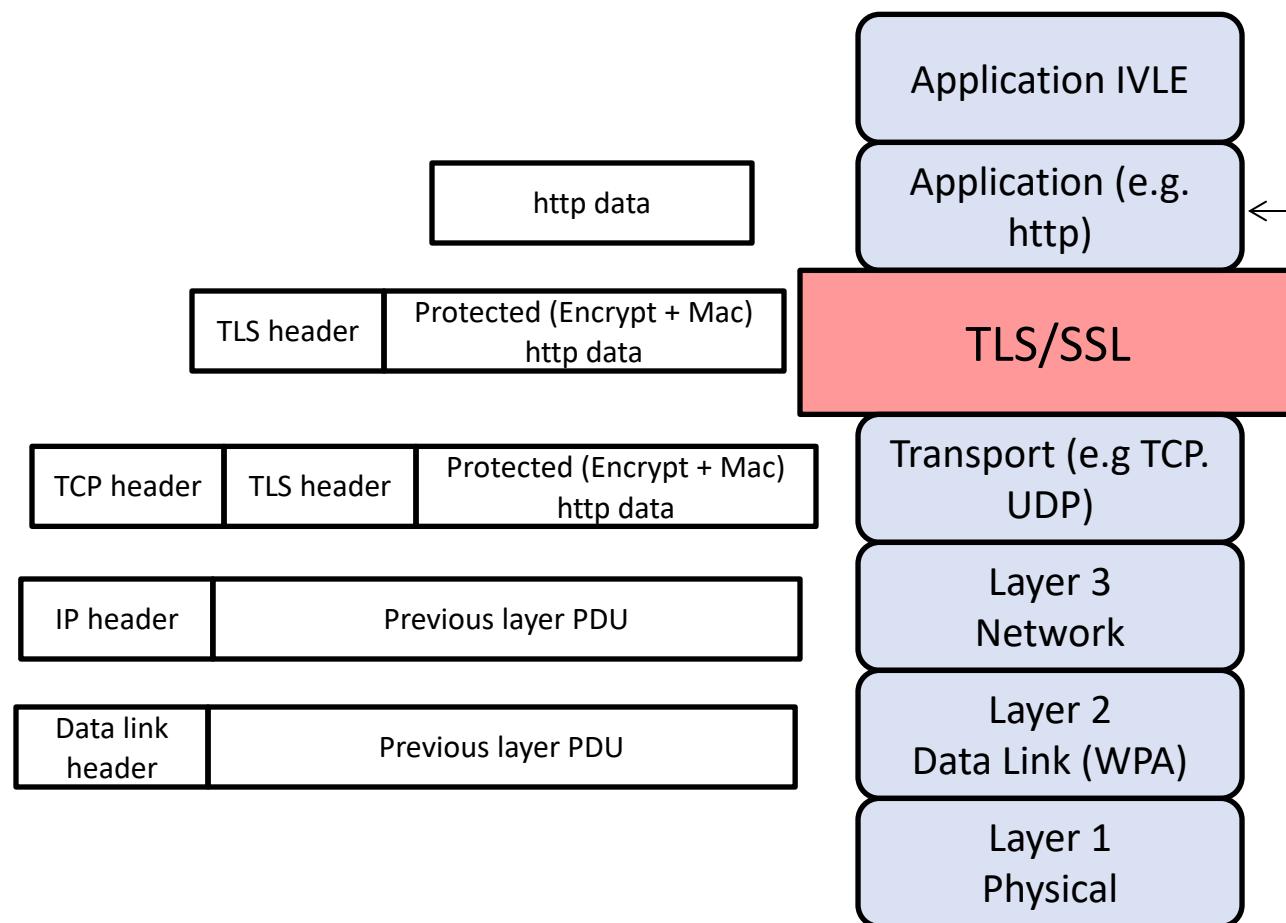

- Suppose that there is an adversary in the application layer.  
For example, a malicious java script injected into IVLE and being executed by Alice's browser.
- Question: Can the malicious script learn
  1. Alice's report? <sup>no</sup>
  2. Alice's mac address? (yes and no)

# Attacker at application layer (e.g. Malware in browser)

Alice upload a report

*Malware in application  
(able to sniff and spoof)*

*Security mechanism  
at this layer*

## 2. WPA2

*Wifi Protected Access II (WPA2).* A popular protocol employed in home Wifi access point.

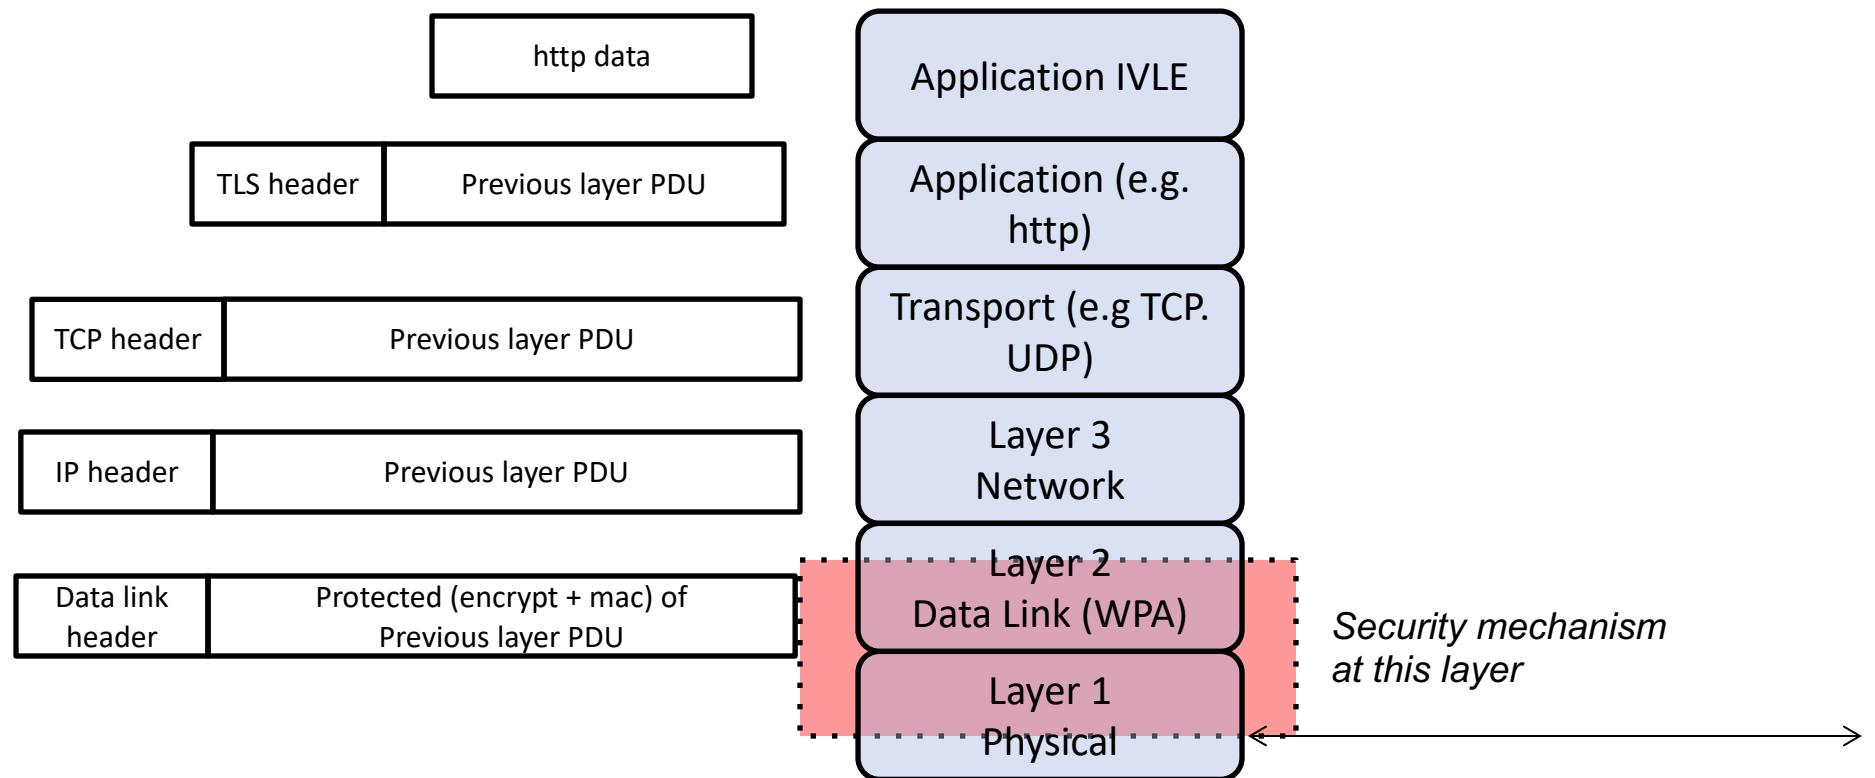

WPA2 provides protection at layer 2 (Link) and layer 1 (Physical). Not all information in layer 2 are protected.

See recent attack on WPA2.

**Key Reinstallation Attacks: Breaking WPA2 by forcing nonce reuse**  
<https://www.krackattacks.com/>

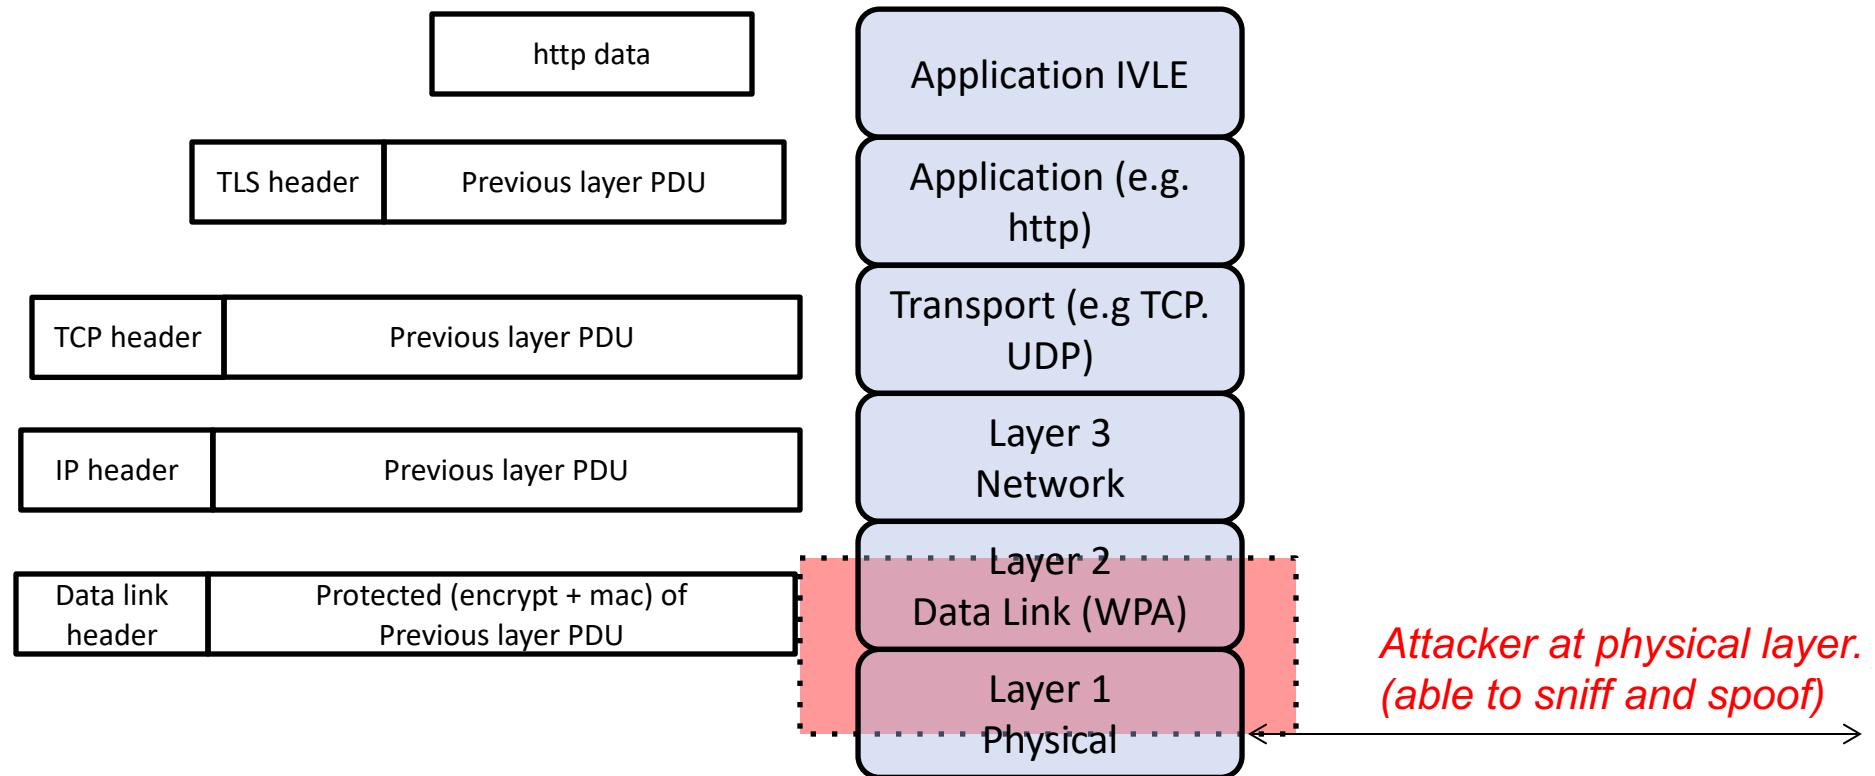

Research paper: <https://papers.mathyvanhoef.com/ccs2017.pdf>

## Alice uploading a report

# Attacker at physical layer

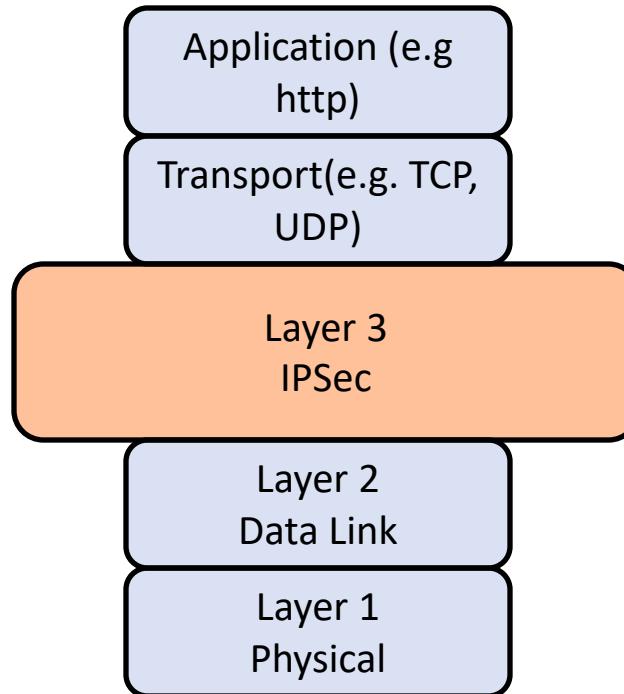

Alice uploading a report

Question: Can the attacker learn

1. Alice's report? no
2. The fact that Alice is visiting IVLE website? no
3. The mac address (link layer)? Not immediately clear from the figure above. Yes.

### 3. IPSec

E.g. IPSec provides “integrity/authenticity” protection of ip-address, but not confidentiality. Hence, attackers are unable to “spoof” the source ip-source, but can learn the source and destination ip-address of the sniffed packets.

# Remarks

- IPSec is a mechanism whose goal is to protect the IP layer.
- “Internet Protocol Security (IPsec) is a protocol suite for securing Internet Protocol (IP) communications by authenticating and encrypting each IP packet of a communication session. IPsec includes protocols for establishing mutual authentication between agents at the beginning of the session and negotiation of cryptographic keys to be used during the session. IPsec can be used in protecting data flows between a pair of hosts (*host-to-host*), between a pair of security gateways (*network-to-network*), or between a security gateway and a host (*network-to-host*).”
- “Internet Protocol security (IPsec) uses cryptographic security services to protect communications over Internet Protocol (IP) networks. IPsec supports network-level peer authentication, data origin authentication, data integrity, data confidentiality (encryption), and replay protection.”
- “IPsec is an end-to-end security scheme operating in the Internet Layer of the Internet Protocol Suite, while some other Internet security systems in widespread use, such as Transport Layer Security (TLS) and Secure Shell (SSH), operate in the upper layers at Application layer. Hence, only IPsec protects any application traffic over an IP network. Applications can be automatically secured by IPsec at the IP layer.”

-wiki

## 5.6. Firewall

[ZCC] ED Zwicky, S Cooper, DB Chapman, **Building Internet Firewalls: Internet and Web Security**, 2000

(free from books.google.com

[http://dbmanagement.info/Books/Others/O%27Reilly\\_Building\\_Internet\\_Firewalls\\_2nd\\_Edition.pdf](http://dbmanagement.info/Books/Others/O%27Reilly_Building_Internet_Firewalls_2nd_Edition.pdf) )

- Consider the computer network in an organization.
  - Some nodes contain more sensitive information than other. Example, Student examination record database server, vs public workstations in lecture hall.
  - Some nodes might have unpatched vulnerabilities. Example, when a patch is available, it might take some time (e.g. days, weeks, months) to patch all the systems.
  - Certain nodes might be compromised (e.g. An unhappy student who has access to the lab's workstation).
  - Certain protocols do not have protection mechanisms, or only light-weight protection. For example, DNS, arp, network printer, etc. We need to prevent attackers from accessing such protocol.
- We need to divide the computer network into segments and deny unnecessary access. (**Principle of least privilege, compartmentalization**)
- Firewall, Intrusion detection system (IDS) are tools to control access to the network.

## Remark: Principle of least privilege and compartmentalization

- The term “Principle of least privilege” was introduced in the design of OS, but was later adopted in other domain in security.
  - “The **principle of least privilege (PoLP**, also known as the **principle of minimal privilege** or the **principle of least authority**) requires that in a particular abstraction layer of a computing environment, every module (such as a process, a user, or a program, depending on the subject) must be able to access only the information and resources that are necessary for its legitimate purpose”  
[https://en.wikipedia.org/wiki/Principle\\_of\\_least\\_privilege#Implementation](https://en.wikipedia.org/wiki/Principle_of_least_privilege#Implementation)
- Compartmentalization: There isn’t a single well accepted definition. Generally, it refer to the notion of confining information within compartments.

# Firewall

set of rules

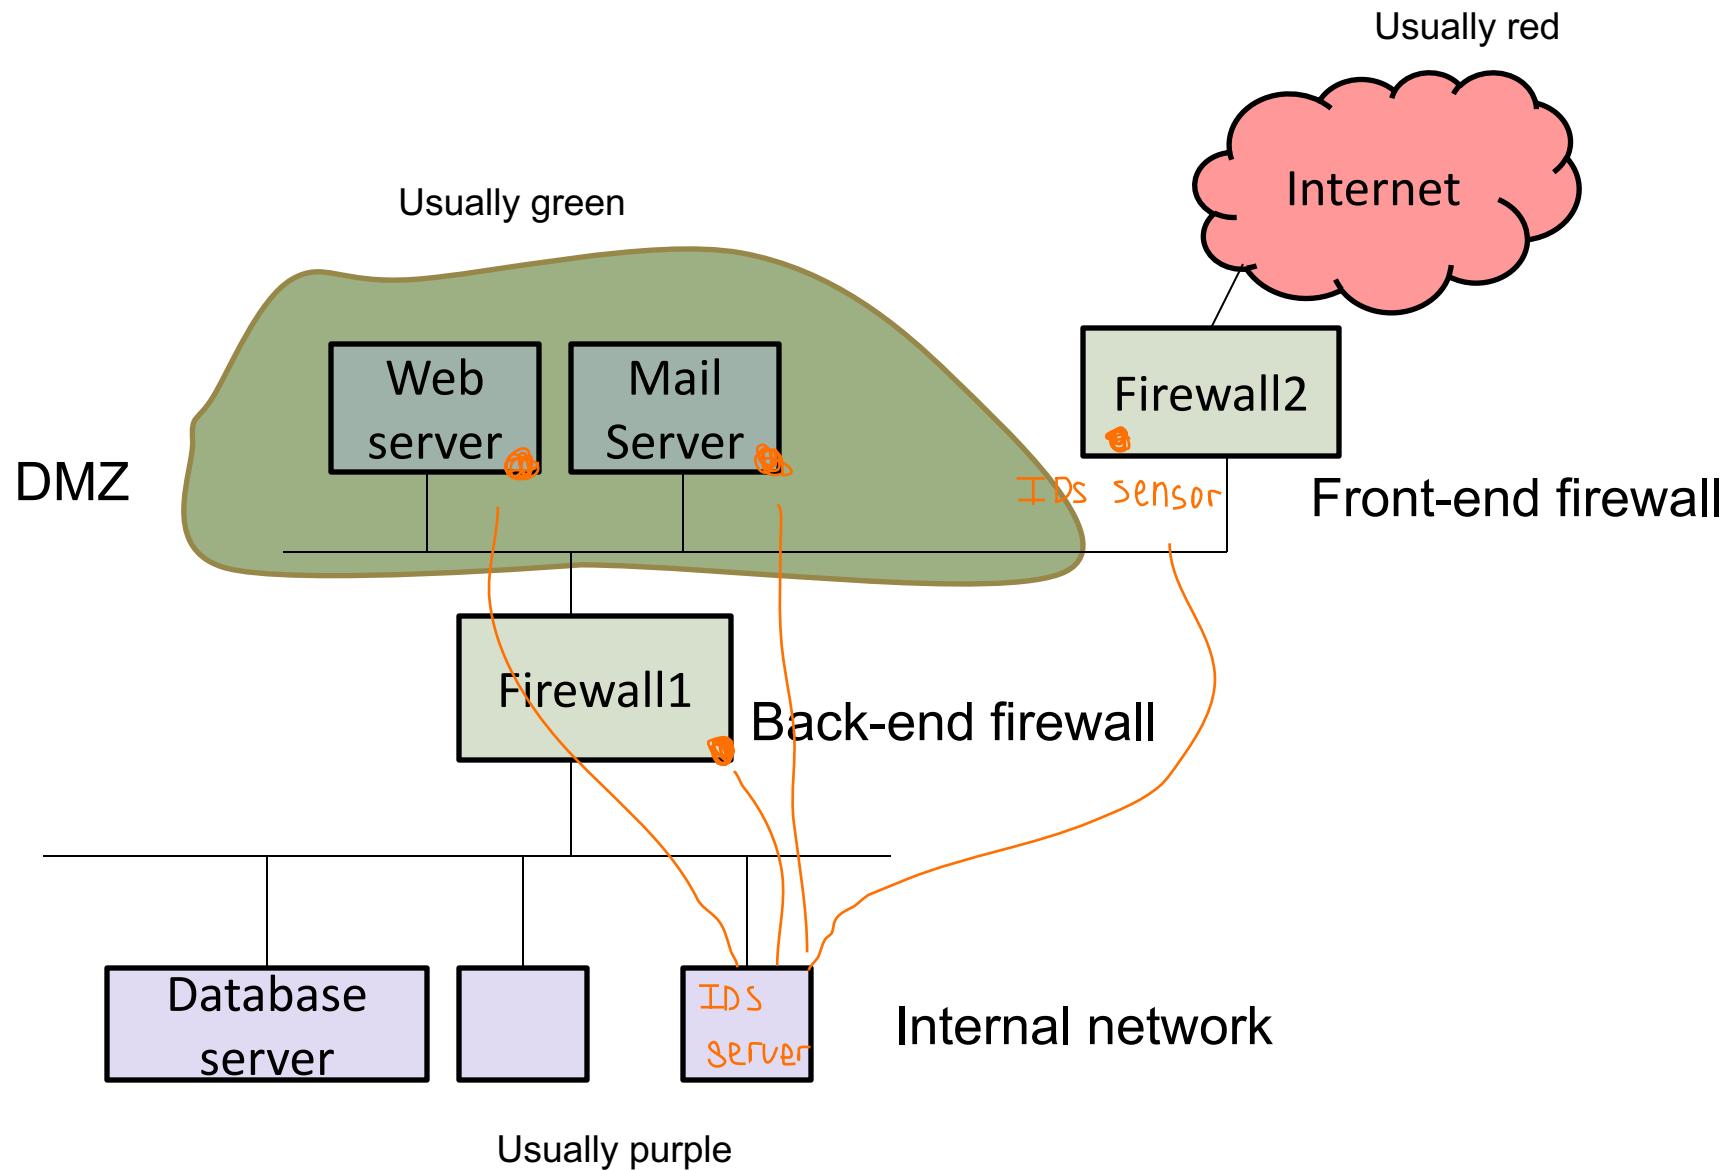

- Firewall: A Firewall controls what traffic is allowed to enter the network (*ingress* filtering), or leave the network (*egress* filtering).
- *Firewall are devices or programs that control the flow of network traffic between networks or hosts that employ differing security postures.*

(from Guidelines on Firewalls and Firewall Policy, NIST, special publication 800-41

<http://csrc.nist.gov/publications/nistpubs/800-41-Rev1/sp800-41-rev1.pdf> )

- DMZ: Demilitarized zone. A sub-network that exposes the organization's external service to the (untrusted) Internet.

# A typical 2-firewall setting.

## Packet filtering/screening ([ZCC Section 5.2])

Firewall's controls are achieved by “packets filtering” (aka screening). Filtering may occur in router, gateway/bridge, host, etc.

Packet filtering inspects every packet, typically only on the IP packet's header information. (if the payload is inspected, we call it ***deep packet inspection (DPI)***). Action taken after inspection could be

- Allow the packet to pass
- Just drop the packet
- Reject the packet (i.e. drop and inform the sender)
- Log info
- Notify system admin
- Modify the packet (for more advanced device).

# Example of firewall rules

- Drop packets with “source ip-address” not within the organization’s network. (*To stop attacks originated within the network*).
- Whitelist
  - Drop all packets except those specified in the white-list. (e.g. drop all except http, email protocol, and DNS)
- Blacklist
  - Accept all packets except those specified in the black-list. (e.g. allow https except ip-address in the black list).

# Firewall design (see [ZCC] ch8.5-12)

A firewall enforces a set of rules provided by the network administrator.

Example on the 2-firewall setting:

- Rules for Firewall1.
    - Block: HTTP.
    - Allow internal to Mail Server: SMTP, POP3
  - Rules for Firewall2
    - Allow from anywhere to Mail Server: SMTP only
- port number usually very important  
-http = 80  
-email = 25

How the rules are to be specified differ on different devices and software. In this lecture, we consider a typical design (from [PF] pg 453)

usually arranged in a sequence

Rule	Type	Direction	Source Address	Destination Address	Designation Port	Action
1	TCP	in	*	192.168.1.*	25	Permit
2	TCP	in	*	192.168.1.*	69	Permit
3	TCP	out	192.168.1.*	*	80	Permit
4	TCP	in	*	192.168.1.18	80	Permit
5	TCP	in	*	192.168.1.*	*	Deny
6	UDP	in	*	192.168.1.*	*	Deny

- The rules are processed sequentially starting from rule 1, 2, .... The first matching rule determines the action.
  - The symbol “\*” matches any value. This is a symbol in “regular expression”.

# Types of firewall

- NIST's document (NIST 800-41) groups the firewalls into 3 types:
  1. **Packet filters** (Inspect packet header)
  2. **Stateful Inspection** (Deep packet inspection)
  3. **Proxy** (Modify packets)

# Intrusion Detection System (IDS)

see slide 91

An IDS system consists of a set of “sensors” gathering data. Sensors could be in the host, or network router. The data are analyzed for intrusion.

Three types of IDS:

- Attack signature Detection
  - The attack has specific, well-defined signature. For e.g. using certain port number, certain source ip address.
- Anomaly Detection
  - The IDS attempt to detect abnormal pattern. For e.g. a sudden surge of packets with certain port number.
- Behavior-based IDS
  - Can be viewed as a type of anomaly detection that focuses on human behavior. For e.g. The system might keep the profile of each user. It then tries to detect any user who deviates from the profile (e.g. start to download large files).

Popular open-source IDS: Snort. <https://www.snort.org/>

e.g. of snort rule (from <https://blog.rapid7.com/2016/12/09/understanding-and-configuring-snort-rules/> ):

```
log tcp !192.168.0/24 any -> 192.168.0.33 (msg: "mounted access" ; )
```

# **Other tools.**

## TLS/SSL scan

- Checking known vulnerability of a server.
- <https://www.ssllabs.com/ssltest/analyze.html?d=luminus.nus.edu.sg&hideResults=on>

## 5.7 Management

- Management needed in order to monitor and adjust network characteristic.
- Detail omitted. Optional. see [PF6.9]

Some terminologies:

- **Security Operations Center (SOC)**
  - a centralized unit in an organization that monitors the IT systems and deals with security issues.
- **Security Information and Event Management (SIEM)**
  - pronounced as “SIM”. Approaches and tools for SOC.
  - A popular system: Splunk ( <https://www.splunk.com/> )  
ELK Stack-Elasticsearch and Kibana (open sourced)
